Sahara project aims to provide users with simple means to provision a Hadoop cluster at OpenStack by specifying several parameters like Hadoop version, cluster topology, nodes hardware details and a few more.

Contents 1

2 Contents

## **Overview**

#### 1.1 Rationale

#### 1.1.1 Introduction

Apache Hadoop is an industry standard and widely adopted MapReduce implementation. The aim of this project is to enable users to easily provision and manage Hadoop clusters on OpenStack. It is worth mentioning that Amazon provides Hadoop for several years as Amazon Elastic MapReduce (EMR) service.

Sahara aims to provide users with simple means to provision Hadoop clusters by specifying several parameters like Hadoop version, cluster topology, nodes hardware details and a few more. After user fills in all the parameters, Sahara deploys the cluster in a few minutes. Also Sahara provides means to scale already provisioned cluster by adding/removing worker nodes on demand.

The solution will address following use cases:

- fast provisioning of Hadoop clusters on OpenStack for Dev and QA;
- utilization of unused compute power from general purpose OpenStack IaaS cloud;
- "Analytics as a Service" for ad-hoc or bursty analytic workloads (similar to AWS EMR).

#### Key features are:

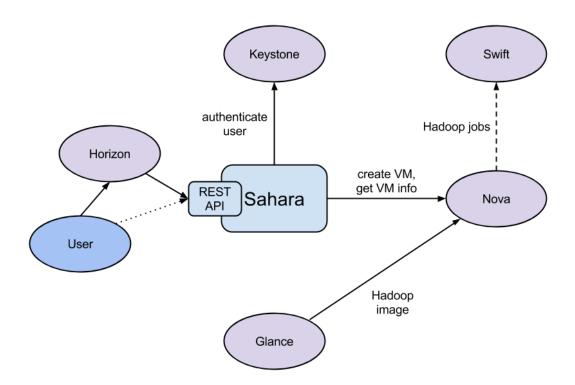

- designed as an OpenStack component;
- managed through REST API with UI available as part of OpenStack Dashboard;
- support for different Hadoop distributions:
  - pluggable system of Hadoop installation engines;
  - integration with vendor specific management tools, such as Apache Ambari or Cloudera Management Console;
- predefined templates of Hadoop configurations with ability to modify parameters.

#### 1.1.2 Details

The Sahara product communicates with the following OpenStack components:

- Horizon provides GUI with ability to use all of Sahara's features.
- Keystone authenticates users and provides security token that is used to work with the OpenStack, hence limiting user abilities in Sahara to his OpenStack privileges.

- Nova is used to provision VMs for Hadoop Cluster.
- Heat Sahara can be configured to use Heat; Heat orchestrates the required services for Hadoop Cluster.
- Glance Hadoop VM images are stored there, each image containing an installed OS and Hadoop. the preinstalled Hadoop should give us good handicap on node start-up.
- Swift can be used as a storage for data that will be processed by Hadoop jobs.
- Cinder can be used as a block storage.
- Neutron provides the networking service.
- · Ceilometer used to collect measures of cluster usage for metering and monitoring purposes.

#### 1.1.3 General Workflow

Sahara will provide two level of abstraction for API and UI based on the addressed use cases: cluster provisioning and analytics as a service.

For the fast cluster provisioning generic workflow will be as following:

- select Hadoop version;
- select base image with or without pre-installed Hadoop:
  - for base images without Hadoop pre-installed Sahara will support pluggable deployment engines integrated with vendor tooling;

- you could download prepared up-to-date images from http://sahara-files.mirantis.com/images/upstream/kilo/;
- define cluster configuration, including size and topology of the cluster and setting the different type of Hadoop parameters (e.g. heap size):
  - to ease the configuration of such parameters mechanism of configurable templates will be provided;
- provision the cluster: Sahara will provision VMs, install and configure Hadoop;
- operation on the cluster: add/remove nodes;
- terminate the cluster when it's not needed anymore.

For analytic as a service generic workflow will be as following:

- select one of predefined Hadoop versions;
- configure the job:
  - choose type of the job: pig, hive, jar-file, etc.;
  - provide the job script source or jar location;
  - select input and output data location (initially only Swift will be supported);
  - select location for logs;
- set limit for the cluster size;
- execute the job:
  - all cluster provisioning and job execution will happen transparently to the user;
  - cluster will be removed automatically after job completion;
- get the results of computations (for example, from Swift).

## 1.1.4 User's Perspective

While provisioning cluster through Sahara, user operates on three types of entities: Node Group Templates, Cluster Templates and Clusters.

A Node Group Template describes a group of nodes within cluster. It contains a list of hadoop processes that will be launched on each instance in a group. Also a Node Group Template may provide node scoped configurations for those processes. This kind of templates encapsulates hardware parameters (flavor) for the node VM and configuration for Hadoop processes running on the node.

A Cluster Template is designed to bring Node Group Templates together to form a Cluster. A Cluster Template defines what Node Groups will be included and how many instances will be created in each. Some of Hadoop Configurations can not be applied to a single node, but to a whole Cluster, so user can specify this kind of configurations in a Cluster Template. Sahara enables user to specify which processes should be added to an anti-affinity group within a Cluster Template. If a process is included into an anti-affinity group, it means that VMs where this process is going to be launched should be scheduled to different hardware hosts.

The Cluster entity represents a Hadoop Cluster. It is mainly characterized by VM image with pre-installed Hadoop which will be used for cluster deployment. User may choose one of pre-configured Cluster Templates to start a Cluster. To get access to VMs after a Cluster has started, user should specify a keypair.

Sahara provides several constraints on Hadoop cluster topology. JobTracker and NameNode processes could be run either on a single VM or two separate ones. Also cluster could contain worker nodes of different types. Worker nodes could run both TaskTracker and DataNode, or either of these processes alone. Sahara allows user to create cluster with any combination of these options, but it will not allow to create a non working topology, for example: a set of workers with DataNodes, but without a NameNode.

1.1. Rationale 5

Each Cluster belongs to some tenant determined by user. Users have access only to objects located in tenants they have access to. Users could edit/delete only objects they created. Naturally admin users have full access to every object. That way Sahara complies with general OpenStack access policy.

## 1.1.5 Integration with Swift

The Swift service is a standard object storage in OpenStack environment, analog of Amazon S3. As a rule it is deployed on bare metal machines. It is natural to expect Hadoop on OpenStack to process data stored there. And it is so. With a FileSystem implementation for Swift HADOOP-8545 and Change I6b1ba25b which implements the ability to list endpoints for an an object, account or container, to make it possible to integrate swift with software that relies on data locality information to avoid network overhead.

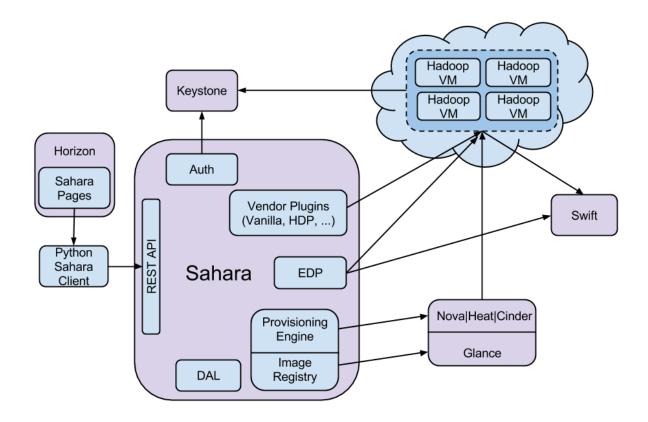

To get more information on how to enable Swift support see Swift Integration.

## 1.1.6 Pluggable Deployment and Monitoring

In addition to the monitoring capabilities provided by vendor-specific Hadoop management tooling, Sahara will provide pluggable integration with external monitoring systems such as Nagios or Zabbix.

Both deployment and monitoring tools will be installed on stand-alone VMs, thus allowing a single instance to manage/monitor several clusters at once.

## 1.2 Architecture

The Sahara architecture consists of several components:

- · Auth component responsible for client authentication & authorization, communicates with Keystone
- DAL Data Access Layer, persists internal models in DB
- Provisioning Engine component responsible for communication with Nova, Heat, Cinder and Glance
- Vendor Plugins pluggable mechanism responsible for configuring and launching Hadoop on provisioned VMs;
   existing management solutions like Apache Ambari and Cloudera Management Console could be utilized for that matter
- EDP *Elastic Data Processing (EDP)* responsible for scheduling and managing Hadoop jobs on clusters provisioned by Sahara
- REST API exposes Sahara functionality via REST
- Python Sahara Client similar to other OpenStack components Sahara has its own python client
- Sahara pages GUI for the Sahara is located on Horizon

1.2. Architecture 7

## **User guide**

#### Installation

## 2.1 Sahara Installation Guide

We recommend installing sahara in a way that will keep your system in a consistent state. We suggest the following options:

- · Install via Fuel
- Install via RDO
- Install into a virtual environment

### 2.1.1 To install with Fuel

- 1. Start by following the MOS Quickstart to install and setup OpenStack.
- 2. Enable the sahara service during installation.

## 2.1.2 To install with RDO

- 1. Start by following the RDO Quickstart to install and setup OpenStack.
- 2. Install sahara:
- # yum install openstack-sahara
  - 3. Configure sahara as needed. The configuration file is located in /etc/sahara/sahara.conf. For details see *Sahara Configuration Guide*
  - 4. Create the database schema:
- # sahara-db-manage --config-file /etc/sahara/sahara.conf upgrade head
  - 5. Go through Common installation steps and make any necessary changes.
  - 6. Start the sahara-all service:
- # systemctl start openstack-sahara-all
  - 7. (Optional) Enable sahara to start on boot

# systemctl enable openstack-sahara-all

#### 2.1.3 To install into a virtual environment

- 1. First you need to install a number of packages with your OS package manager. The list of packages depends on the OS you use. For Ubuntu run:
- \$ sudo apt-get install python-setuptools python-virtualenv python-dev

#### For Fedora:

\$ sudo yum install gcc python-setuptools python-virtualenv python-devel

#### For CentOS:

- \$ sudo yum install gcc python-setuptools python-devel
- \$ sudo easy\_install pip
- \$ sudo pip install virtualenv
  - 2. Setup a virtual environment for sahara:
- \$ virtualenv sahara-venv

This will install a python virtual environment into sahara-venv directory in your current working directory. This command does not require super user privileges and can be executed in any directory where the current user has write permissions.

- 3. You can install the latest sahara release from pypi:
- \$ sahara-venv/bin/pip install sahara

Or you can get a sahara archive from http://tarballs.openstack.org/sahara/ and install it using pip:

\$ sahara-venv/bin/pip install 'http://tarballs.openstack.org/sahara/sahara-master.tar.gz'

Note that sahara-master.tar.gz contains the latest changes and might not be stable at the moment. We recommend browsing http://tarballs.openstack.org/sahara/ and selecting the latest stable release.

- 4. After installation you should create a configuration file from the sample file located in sahara-venv/share/sahara/sahara.conf.sample-basic:
- \$ mkdir sahara-venv/etc
- \$ cp sahara-venv/share/sahara/sahara.conf.sample-basic sahara-venv/etc/sahara.conf

Make any necessary changes to sahara-venv/etc/sahara.conf. For details see Sahara Configuration Guide

### 2.1.4 Common installation steps

The steps below are common to both the RDO and virtual environment installations of sahara.

1. If you use sahara with a MySQL database, then for storing big job binaries in the sahara internal database you must configure the size of the maximum allowed packet. Edit the my.cnf file and change the max allowed packet parameter as follows:

```
...
[mysqld]
...
max_allowed_packet = 256M
```

Then restart the mysql server to ensure these changes are active.

- 2. Create the database schema:
- \$ sahara-venv/bin/sahara-db-manage --config-file sahara-venv/etc/sahara.conf upgrade head
  - 3. To start sahara call:
- \$ sahara-venv/bin/sahara-all --config-file sahara-venv/etc/sahara.conf
  - 4. For sahara to be accessible in the OpenStack Dashboard and for python-saharaclient to work properly you must register sahara in the Identity service catalog. For example:

```
keystone service-create --name sahara --type data-processing \
    --description "Sahara Data Processing"

keystone endpoint-create --service sahara --region RegionOne \
    --publicurl "http://10.0.0.2:8386/v1.1/%(tenant_id)s" \
    --adminurl "http://10.0.0.2:8386/v1.1/%(tenant_id)s" \
    --internalurl "http://10.0.0.2:8386/v1.1/%(tenant_id)s"
```

5. For more information on configuring sahara with the OpenStack Dashboard please see *OpenStack Dashboard Configuration Guide*.

#### 2.1.5 Notes:

Ensure that your operating system is not blocking the sahara port (default: 8386). You may need to configure iptables in CentOS and other Linux distributions to allow this access.

To get the list of all possible options run:

```
$ sahara-venv/bin/python sahara-venv/bin/sahara-all --help
```

Further, consider reading *Getting Started* for general sahara concepts and *Provisioning Plugins* for specific plugin features/requirements.

## 2.2 Sahara Configuration Guide

This guide covers the steps for a basic configuration of sahara. It will help you to configure the service in the most simple manner.

#### 2.2.1 Basic configuration

Sahara is packaged with a basic sample configration file: sahara.conf.sample-basic. This file contains all the essential parameters that are required for sahara. We recommend creating your configuration file based on this basic example.

If a more thorough configuration is needed we recommend using the tox tool to create a full configuration file by executing the following command:

```
$ tox -e genconfig
```

Running this command will create a file named sahara.conf.sample in the etc/sahara directory of the project.

After creating a configuration file by either copying the basic example or generating one, edit the connection parameter in the [database] section. The URL provided here should point to an empty database. For example, the connection string for a MySQL database will be:

```
connection=mysql://username:password@host:port/database
```

Next you will configure the Identity service parameters in the [keystone\_authtoken] section. The auth\_uri parameter should point to the public Identity API endpoint. The identity\_uri should point to the admin Identity API endpoint. For example:

```
auth_uri=http://127.0.0.1:5000/v2.0/
identity_uri=http://127.0.0.1:35357/
```

Specify the admin\_user, admin\_password and admin\_tenant\_name. These parameters must specify an Identity user who has the admin role in the given tenant. These credentials allow sahara to authenticate and authorize its users.

Next you will configure the default Networking service. If using neutron for networking the following parameter should be set in the [DEFAULT] section:

```
use neutron=true
```

If you are using nova-network for networking then this parameter should be set to false.

With these paramaters set, sahara is ready to run.

If you wish to increase the logging levels for troubleshooting there are two parameters in the <code>[DEFAULT]</code> section of the configuration file which control the level of logging output; <code>verbose</code> and <code>debug</code>. With <code>verbose</code> set to <code>true</code> sahara's default logging level will be set to INFO, and with <code>debug</code> set to <code>true</code> it will be set to DEBUG. By default the sahara's log level is set to WARNING.

## 2.2.2 Networking configuration

By default sahara is configured to use the nova-network implementation of OpenStack Networking. If an OpenStack cluster uses Neutron, then the use\_neutron parameter should be set to True in the sahara configuration file. Additionally, if the cluster supports network namespaces the use\_namespaces property can be used to enable their usage.

```
[DEFAULT]
```

```
use_neutron=True
use_namespaces=True
```

**Note:** If a user other than root will be running the Sahara server instance and namespaces are used, some additional configuration is required, please see *Non-root users* for more information.

#### Floating IP management

During cluster setup sahara must access instances through a secure shell(SSH). To establish this connection it may use either the fixed or floating IP address of an instance. By default sahara is configured to use floating IP addresses for access. This is controlled by the use\_floating\_ips configuration parameter. With this setup the user has two options for ensuring that all instances gain a floating IP address:

- If using the nova-network, it may be configured to assign floating IP addresses automatically by setting the auto\_assign\_floating\_ip parameter to True in the nova configuration file (usually nova.conf).
- The user may specify a floating IP address pool for each node group directly.

**Warning:** When using floating IP addresses for management (use\_floating\_ip=True) **every** instance in the cluster must have a floating IP address, otherwise sahara will not be able to utilize that cluster.

If not using floating IP addresses (use\_floating\_ip=False) sahara will use fixed IP addresses for instance management. When using neutron for the Networking service the user will be able to choose the fixed IP network for all instances in a cluster. Whether using nova-network or neutron it is important to ensure that all instances running sahara have access to the fixed IP networks.

## 2.2.3 Notifications configuration

Sahara can be configured to send notifications to the OpenStack Telemetry module. To enable this functionality the following parameters should be set in the <code>[DEFAULT]</code> section of the configuration file:

```
enable_notifications = true
notification_driver = messaging
```

By default sahara is configured to use RabbitMQ as its message broker, but it can be configured to use Qpid instead if needed

If you are using RabbitMQ as the message broker, then you should set the following parameter in the [DEFAULT] section:

```
rpc_backend = rabbit
```

You may also need to specify the connection parameters for your RabbitMQ installation. The following example shows the default values in the [oslo\_messaging\_rabbit] section which may need adjustment:

```
rabbit_host=localhost
rabbit_port=5672
rabbit_hosts=$rabbit_host:$rabbit_port
rabbit_userid=guest
rabbit_password=guest
rabbit_virtual_host=/
```

If you are using Qpid as the message broker, then you should set the rpc\_backend as follows:

```
rpc_backend = qpid
```

You may also need to adjust the following default connection parameters in the [oslo\_messaging\_qpid] section:

```
qpid_hostname=localhost
qpid_port=5672
qpid_hosts=$qpid_hostname:$qpid_port
qpid_username=
qpid_password=
```

## 2.2.4 Orchestration configuration

By default sahara is configured to use the direct engine for instance creation. This engine makes calls directly to the services required for instance provisioning. Sahara can be configured to use the OpenStack Orchestration service for this task instead of the direct engine.

To configure sahara to utilize the Orchestration service for instance provisioning the infrastructure\_engine parameter should be modified in the configuration file as follows:

```
[DEFAULT]
infrastructure_engine=heat
```

There is feature parity between the direct and heat infrastructure engines. We recommend using the heat engine for provisioning as the direct is planned for deprecation.

## 2.2.5 Policy configuration

Sahara's public API calls may be restricted to certain sets of users by using a policy configuration file. The location of the policy file(s) is controlled by the policy\_file and policy\_dirs parameters in the [oslo\_policy] section. By default sahara will search for a policy.json file in the same directory as the configuration file.

#### **Examples**

Example 1. Allow all method to all users (default policy).

```
"default": ""
}
```

Example 2. Disallow image registry manipulations to non-admin users.

```
"default": "",

"images:register": "role:admin",
    "images:unregister": "role:admin",
    "images:add_tags": "role:admin",
    "images:remove_tags": "role:admin"]
```

## 2.3 OpenStack Dashboard Configuration Guide

Sahara UI panels are integrated into the OpenStack Dashboard repository. No additional steps are required to enable Sahara UI in OpenStack Dashboard. However there are a few configurations that should be made to configure OpenStack Dashboard.

Dashboard configurations are applied through the local\_settings.py file. The sample configuration file is available here.

## 2.3.1 1. Networking

Depending on the Networking backend (Nova Network or Neutron) used in the cloud, Sahara panels will determine automatically which input fields should be displayed.

While using Nova Network backend the cloud may be configured to automatically assign floating IPs to instances. If Sahara service is configured to use those automatically assigned floating IPs the same configuration should be done to the dashboard through the SAHARA\_AUTO\_IP\_ALLOCATION\_ENABLED parameter.

#### Example:

```
SAHARA_AUTO_IP_ALLOCATION_ENABLED = True
```

## 2.3.2 2. Different endpoint

Sahara UI panels normally use data\_processing endpoint from Keystone to talk to Sahara service. In some cases it may be useful to switch to another endpoint, for example use locally installed Sahara instead of the one on the OpenStack controller.

To switch the UI to another endpoint the endpoint should be registered in the first place.

Local endpoint example:

```
keystone service-create --name sahara_local --type data_processing_local \
    --description "Sahara Data Processing (local installation)"

keystone endpoint-create --service sahara_local --region RegionOne \
    --publicurl "http://127.0.0.1:8386/v1.1/% (tenant_id)s" \
    --adminurl "http://127.0.0.1:8386/v1.1/% (tenant_id)s" \
    --internalurl "http://127.0.0.1:8386/v1.1/% (tenant_id)s"
```

Then the endpoint name should be changed in sahara.py under the openstack\_dashboard.api module.

```
# "type" of Sahara service registered in keystone
SAHARA_SERVICE = 'data_processing_local'
```

## 2.4 Sahara Advanced Configuration Guide

This guide addresses specific aspects of Sahara configuration that pertain to advanced usage. It is divided into sections about various features that can be utilized, and their related configurations.

## 2.4.1 Custom network topologies

Sahara accesses instances at several stages of cluster spawning through SSH and HTTP. Floating IPs and network namespaces (see *Networking configuration*) will be automatically used for access when present. When floating IPs are not assigned to instances and namespaces are not being used, sahara will need an alternative method to reach them.

The proxy\_command parameter of the configuration file can be used to give sahara a command to access instances. This command is run on the sahara host and must open a netcat socket to the instance destination port. The {host} and {port} keywords should be used to describe the destination, they will be substituted at runtime. Other keywords that can be used are: {tenant\_id}, {network\_id} and {router\_id}.

For example, the following parameter in the sahara configuration file would be used if instances are accessed through a relay machine:

```
[DEFAULT]
proxy_command='ssh relay-machine-{tenant_id} nc {host} {port}'
```

Whereas the following shows an example of accessing instances though a custom network namespace:

```
[DEFAULT]
proxy_command='ip netns exec ns_for_{network_id} nc {host} {port}'
```

## 2.4.2 Data-locality configuration

Hadoop provides the data-locality feature to enable task tracker and data nodes the capability of spawning on the same rack, Compute node, or virtual machine. Sahara exposes this functionality to the user through a few configuration parameters and user defined topology files.

To enable data-locality, set the enable\_data\_locality parameter to True in the sahara configuration file

#### [DEFAULT]

```
enable_data_locality=True
```

With data locality enabled, you must now specify the topology files for the Compute and Object Storage services. These files are specified in the sahara configuration file as follows:

#### [DEFAULT]

```
compute_topology_file=/etc/sahara/compute.topology
swift_topology_file=/etc/sahara/swift.topology
```

The compute\_topology\_file should contain mappings between Compute nodes and racks in the following format:

```
compute1 /rack1
compute1 /rack2
compute1 /rack2
```

Note that the Compute node names must be exactly the same as configured in OpenStack (host column in admin list for instances).

The swift\_topology\_file should contain mappings between Object Storage nodes and racks in the following format:

```
node1 /rack1
node2 /rack2
node3 /rack2
```

Note that the Object Storage node names must be exactly the same as configured in the object ring. Also, you should ensure that instances with the task tracker process have direct access to the Object Storage nodes.

Hadoop versions after 1.2.0 support four-layer topology (for more detail please see HADOOP-8468 JIRA issue). To enable this feature set the <code>enable\_hypervisor\_awareness</code> parameter to <code>True</code> in the configuration file. In this case sahara will add the Compute node ID as a second level of topology for virtual machines.

#### 2.4.3 Distributed mode configuration

Sahara can be configured to run in a distributed mode that creates a separation between the API and engine processes. This allows the API process to remain relatively free to handle requests while offloading intensive tasks to the engine processes.

The sahara-api application works as a front-end and serves user requests. It offloads 'heavy' tasks to the sahara-engine process via RPC mechanisms. While the sahara-engine process could be loaded with tasks, sahara-api stays free and hence may quickly respond to user queries.

If sahara runs on several hosts, the API requests could be balanced between several sahara-api hosts using a load balancer. It is not required to balance load between different sahara-engine hosts as this will be automatically done via the message broker.

If a single host becomes unavailable, other hosts will continue serving user requests. Hence, a better scalability is achieved and some fault tolerance as well. Note that distributed mode is not a true high availability. While the failure of a single host does not affect the work of the others, all of the operations running on the failed host will stop. For example, if a cluster scaling is interrupted, the cluster will be stuck in a half-scaled state. The cluster might continue working, but it will be impossible to scale it further or run jobs on it via EDP.

To run sahara in distributed mode pick several hosts on which you want to run sahara services and follow these steps:

• On each host install and configure sahara using the installation guide except:

- Do not run sahara-db-manage or launch sahara with sahara-all
- Ensure that each configuration file provides a database connection string to a single database for all hosts.
- Run sahara-db-manage as described in the installation guide, but only on a single (arbitrarily picked) host.
- The sahara-api and sahara-engine processes use oslo.messaging to communicate with each other. You will need to configure it properly on each host (see below).
- Run sahara-api and sahara-engine on the desired hosts. You may run both processes on the same or separate hosts as long as they are configured to use the same message broker and database.

To configure oslo.messaging, first you will need to choose a message broker driver. Currently there are three drivers provided: RabbitMQ, Qpid or ZeroMQ. For the RabbitMQ or Qpid drivers please see the *Notifications configuration* documentation for an explanation of common configuration options.

For an expanded view of all the options provided by each message broker driver in oslo.messaging please refer to the options available in the respective source trees:

- · For Rabbit MQ see
  - rabbit\_opts variable in impl\_rabbit.py
  - amqp\_opts variable in amqp.py
- · For Qpid see
  - qpid\_opts variable in impl\_qpid.py
  - amqp\_opts variable in amqp.py
- For Zmq see
  - zmq\_opts variable in impl\_zmq.py
  - matchmaker\_opts variable in matchmaker.py
  - matchmaker\_redis\_opts variable in matchmaker\_redis.py
  - matchmaker\_opts variable in matchmaker\_ring.py

These options will also be present in the generated sample configuration file. For instructions on creating the configuration file please see the *Sahara Configuration Guide*.

## 2.4.4 External key manager usage (EXPERIMENTAL)

Sahara generates and stores several passwords during the course of operation. To harden sahara's usage of passwords it can be instructed to use an external key manager for storage and retrieval of these secrets. To enable this feature there must first be an OpenStack Key Manager service deployed within the stack. Currently, the barbican project is the only key manager supported by sahara.

With a Key Manager service deployed on the stack, sahara must be configured to enable the external storage of secrets. This is accomplished by editing the sahara configuration file as follows:

#### [DEFAULT]

use\_external\_key\_manager=True

Additionally, at this time there are two more values which must be provided to ensure proper access for sahara to the Key Manager service. These are the Identity domain for the administrative user and the domain for the administrative project. By default these values will appear as:

#### [DEFAULT]

admin\_user\_domain\_name=default
admin\_project\_domain\_name=default

With all of these values configured and the Key Manager service deployed, sahara will begin storing its secrets in the external manager.

## 2.4.5 Indirect instance access through proxy nodes

Warning: The indirect VMs access feature is in alpha state. We do not recommend using it in a production environment.

Sahara needs to access instances through SSH during cluster setup. This access can be obtained a number of different ways (see *Networking configuration*, *Floating IP management*, *Custom network topologies*). Sometimes it is impossible to provide access to all nodes (because of limited numbers of floating IPs or security policies). In these cases access can be gained using other nodes of the cluster as proxy gateways. To enable this set <code>is\_proxy\_gateway=True</code> for the node group you want to use as proxy. Sahara will communicate with all other cluster instances through the instances of this node group.

Note, if use\_floating\_ips=true and the cluster contains a node group with is\_proxy\_gateway=True, the requirement to have floating\_ip\_pool specified is applied only to the proxy node group. Other instances will be accessed through proxy instances using the standard private network.

Note, the Cloudera Hadoop plugin doesn't support access to Cloudera manager through a proxy node. This means that for CDH clusters only nodes with the Cloudera manager can be designated as proxy gateway nodes.

## 2.4.6 Multi region deployment

Sahara supports multi region deployment. To enable this option each instance of sahara should have the os\_region\_name=<region> parameter set in the configuration file. The following example demonstrates configuring sahara to use the RegionOne region:

#### [DEFAULT]

os\_region\_name=RegionOne

#### 2.4.7 Non-root users

In cases where a proxy command is being used to access cluster instances (for example, when using namespaces or when specifying a custom proxy command), rootwrap functionality is provided to allow users other than root access to the needed operating system facilities. To use rootwrap the following configuration parameter is required to be set:

#### [DEFAULT]

use\_rootwrap=True

Assuming you elect to leverage the default rootwrap command (sahara-rootwrap), you will need to perform the following additional setup steps:

• Copy the provided sudoers configuration file from the local project file etc/sudoers.d/sahara-rootwrap to the system specific location, usually /etc/sudoers.d. This file is setup to allow a user named sahara access to the rootwrap script. It contains the following:

```
sahara ALL = (root) NOPASSWD: /usr/bin/sahara-rootwrap /etc/sahara/rootwrap.conf *
```

• Copy the provided rootwrap configuration file from the local project file etc/sahara/rootwrap.conf to the system specific location, usually /etc/sahara. This file contains the default configuration for rootwrap.

• Copy the provided rootwrap filters file from the local project file etc/sahara/rootwrap.d/sahara.filters to the location specified in the rootwrap configuration file, usually /etc/sahara/rootwrap.d. This file contains the filters that will allow the sahara user to access the ip netns exec, nc, and kill commands through the rootwrap (depending on proxy command you may need to set additional filters). It should look similar to the followings:

```
[Filters]
ip: IpNetnsExecFilter, ip, root
nc: CommandFilter, nc, root
kill: CommandFilter, kill, root
```

If you wish to use a rootwrap command other than sahara-rootwrap you can set the following parameter in your sahara configuration file:

#### [DEFAULT]

```
rootwrap_command='sudo sahara-rootwrap /etc/sahara/rootwrap.conf'
```

For more information on rootwrap please refer to the official Rootwrap documentation

## 2.4.8 Object Storage access using proxy users

To improve security for clusters accessing files in Object Storage, sahara can be configured to use proxy users and delegated trusts for access. This behavior has been implemented to reduce the need for storing and distributing user credentials.

The use of proxy users involves creating an Identity domain that will be designated as the home for these users. Proxy users will be created on demand by sahara and will only exist during a job execution which requires Object Storage access. The domain created for the proxy users must be backed by a driver that allows sahara's admin user to create new user accounts. This new domain should contain no roles, to limit the potential access of a proxy user.

Once the domain has been created, sahara must be configured to use it by adding the domain name and any potential delegated roles that must be used for Object Storage access to the sahara configuration file. With the domain enabled in sahara, users will no longer be required to enter credentials for their data sources and job binaries referenced in Object Storage.

#### **Detailed instructions**

First a domain must be created in the Identity service to hold proxy users created by sahara. This domain must have an identity backend driver that allows for sahara to create new users. The default SQL engine is sufficient but if your keystone identity is backed by LDAP or similar then domain specific configurations should be used to ensure sahara's access. Please see the Keystone documentation for more information.

With the domain created, sahara's configuration file should be updated to include the new domain name and any potential roles that will be needed. For this example let's assume that the name of the proxy domain is sahara\_proxy and the roles needed by proxy users will be Member and SwiftUser.

#### [DEFAULT]

```
use_domain_for_proxy_users=True
proxy_user_domain_name=sahara_proxy
proxy_user_role_names=Member,SwiftUser
```

A note on the use of roles. In the context of the proxy user, any roles specified here are roles intended to be delegated to the proxy user from the user with access to Object Storage. More specifically, any roles that are required for Object Storage access by the project owning the object store must be delegated to the proxy user for authentication to be successful.

Finally, the stack administrator must ensure that images registered with sahara have the latest version of the Hadoop swift filesystem plugin installed. The sources for this plugin can be found in the sahara extra repository. For more information on images or swift integration see the sahara documentation sections *Building Images for Vanilla Plugin* and *Swift Integration*.

## 2.4.9 Volume instance locality configuration

The Block Storage service provides the ability to define volume instance locality to ensure that instance volumes are created on the same host as the hypervisor. The InstanceLocalityFilter provides the mechanism for the selection of a storage provider located on the same physical host as an instance.

To enable this functionality for instances of a specific node group, the <code>volume\_local\_to\_instance</code> field in the node group template should be set to <code>True</code> and some extra configurations are needed:

- The cinder-volume service should be launched on every physical host and at least one physical host should run both cinder-scheduler and cinder-volume services.
- InstanceLocalityFilter should be added to the list of default filters (scheduler\_default\_filters in cinder) for the Block Storage configuration.
- The Extended Server Attributes extension needs to be active in the Compute service (this is true by default in nova), so that the OS-EXT-SRV-ATTR: host property is returned when requesting instance info.
- The user making the call needs to have sufficient rights for the property to be returned by the Compute service. This can be done by:
  - by changing nova's policy.json to allow the user access to the extended\_server\_attributes option.
  - by designating an account with privileged rights in the cinder configuration:

```
os_privileged_user_name =
os_privileged_user_password =
os_privileged_user_tenant =
```

It should be noted that in a situation when the host has no space for volume creation, the created volume will have an Error state and can not be used.

## 2.5 Sahara Upgrade Guide

This page contains details about upgrading sahara between releases such as configuration file updates, database migrations, and architectural changes.

#### 2.5.1 Icehouse -> Juno

#### Main binary renamed to sahara-all

The All-In-One sahara binary has been renamed from sahara-api to sahara-all. The new name should be used in all cases where the All-In-One sahara is desired.

#### **Authentication middleware changes**

The custom auth\_token middleware has been deprecated in favor of the keystone middleware. This change requires an update to the sahara configuration file. To update your configuration file you should replace the following parameters from the <code>[DEFAULT]</code> section with the new parameters in the <code>[keystone\_authtoken]</code> section:

Old parameter name	New parameter name		
os_admin_username	admin_user		
os_admin_password	admin_password		
os admin tenant name	admin tenant name		

Additionally, the parameters os\_auth\_protocol, os\_auth\_host, and os\_auth\_port have been combined to create the auth\_uri and identity\_uri parameters. These new parameters should be full URIs to the keystone public and admin endpoints, respectively.

For more information about these configuration parameters please see the Sahara Configuration Guide.

#### **Database package changes**

The oslo based code from sahara.openstack.common.db has been replaced by the usage of the oslo.db package. This change does not require any update to sahara's configuration file.

Additionally, the usage of SQLite databases has been deprecated. Please use MySQL or PostgreSQL databases for sahara. SQLite has been deprecated because it does not, and is not going to, support the ALTER COLUMN and DROP COLUMN commands required for migrations between versions. For more information please see http://www.sqlite.org/omitted.html

#### Sahara integration into OpenStack Dashboard

The sahara dashboard package has been deprecated in the Juno release. The functionality of the dashboard has been fully incorporated into the OpenStack Dashboard. The sahara interface is available under the "Project" -> "Data Processing" tab.

The Data processing service endpoints must be registered in the Identity service catalog for the Dashboard to properly recognize and display those user interface components. For more details on this process please see *registering Sahara in installation guide*.

The sahara-dashboard project is now used solely to host sahara user interface integration tests.

#### Virtual machine user name changes

The HEAT infrastructure engine has been updated to use the same rules for instance user names as the direct engine. In previous releases the user name for instances created by sahara using HEAT was always 'ec2-user'. As of Juno, the user name is taken from the image registry as described in the *Registering an Image* document.

This change breaks backward compatibility for clusters created using the HEAT infrastructure engine prior to the Juno release. Clusters will continue to operate, but we do not recommended using the scaling operations with them.

#### Anti affinity implementation changed

Starting with the Juno release the anti affinity feature is implemented using server groups. From the user prespective there will be no noticeable changes with this feature. Internally this change has introduced the following behavior:

1. Server group objects will be created for any clusters with anti affinity enabled.

2. Affected instances on the same host will not be allowed even if they do not have common processes. Prior to Juno, instances with differing processes were allowed on the same host. The new implementation guarantees that all affected instances will be on different hosts regardless of their processes.

The new anti affinity implementation will only be applied for new clusters. Clusters created with previous versions will continue to operate under the older implementation, this applies to scaling operations on these clusters as well.

#### 2.5.2 Juno -> Kilo

#### Sahara requires policy configuration

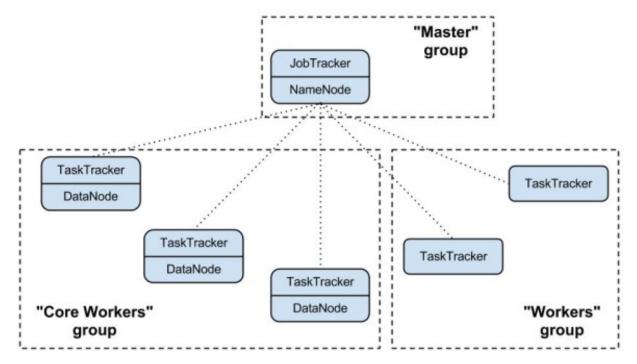

Sahara now requires a policy configuration file. The policy.json file should be placed in the same directory as the sahara configuration file or specified using the policy\_file parameter. For more details about the policy file please see the *policy section in the configuration guide*.

How To

## 2.6 Getting Started

#### 2.6.1 Clusters

A cluster deployed by Sahara consists of node groups. Node groups vary by their role, parameters and number of machines. The picture below illustrates an example of a Hadoop cluster consisting of 3 node groups each having a different role (set of processes).

Node group parameters include Hadoop parameters like *io.sort.mb* or *mapred.child.java.opts*, and several infrastructure parameters like the flavor for VMs or storage location (ephemeral drive or Cinder volume).

A cluster is characterized by its node groups and its parameters. Like a node group, a cluster has Hadoop and infrastructure parameters. An example of a cluster-wide Hadoop parameter is *dfs.replication*. For infrastructure, an example could be image which will be used to launch cluster VMs.

## 2.6.2 Templates

In order to simplify cluster provisioning Sahara employs the concept of templates. There are two kinds of templates: node group templates and cluster templates. The former is used to create node groups, the latter - clusters. Essentially templates have the very same parameters as corresponding entities. Their aim is to remove the burden of specifying all of the required parameters each time a user wants to launch a cluster.

In the REST interface, templates have extended functionality. First you can specify node-scoped parameters here, they will work as a defaults for node groups. Also with the REST interface, during cluster creation a user can override template parameters for both cluster and node groups.

## 2.6.3 Provisioning Plugins

A provisioning plugin is a component responsible for provisioning a Hadoop cluster. Generally each plugin is capable of provisioning a specific Hadoop distribution. Also the plugin can install management and/or monitoring tools for a cluster.

Since Hadoop parameters vary depending on distribution and the Hadoop version, templates are always plugin and Hadoop version specific. A template cannot be used if the plugin/Hadoop versions are different than the ones they were created for.

You may find the list of available plugins on that page: Provisioning Plugins

## 2.6.4 Image Registry

OpenStack starts VMs based on a pre-built image with an installed OS. The image requirements for Sahara depend on the plugin and Hadoop version. Some plugins require just a basic cloud image and will install Hadoop on the VMs from scratch. Some plugins might require images with pre-installed Hadoop.

The Sahara Image Registry is a feature which helps filter out images during cluster creation. See *Registering an Image* for details on how to work with Image Registry.

#### 2.6.5 Features

Sahara has several interesting features. The full list could be found there: Features Overview

## 2.7 Sahara (Data Processing) UI User Guide

This guide assumes that you already have the Sahara service and Horizon dashboard up and running. Don't forget to make sure that Sahara is registered in Keystone. If you require assistance with that, please see the installation guide.

The sections below give a panel by panel overview of setting up clusters and running jobs. For a description of using the guided cluster and job tools, look at Launching a cluster via the Cluster Creation Guide and Running a job via the Job Execution Guide.

## 2.7.1 Launching a cluster via the Sahara UI

## 2.7.2 Registering an Image

- 1. Navigate to the "Project" dashboard, then the "Data Processing" tab, then click on the "Image Registry" panel
- 2. From that page, click on the "Register Image" button at the top right
- 3. Choose the image that you'd like to register with Sahara
- 4. Enter the username of the cloud-init user on the image
- 5. Click on the tags that you want to add to the image. (A version ie: 1.2.1 and a type ie: vanilla are required for cluster functionality)
- 6. Click the "Done" button to finish the registration

## 2.7.3 Create Node Group Templates

- 1. Navigate to the "Project" dashboard, then the "Data Processing" tab, then click on the "Node Group Templates" panel
- 2. From that page, click on the "Create Template" button at the top right
- 3. Choose your desired Plugin name and Version from the dropdowns and click "Create"
- 4. Give your Node Group Template a name (description is optional)
- 5. Choose a flavor for this template (based on your CPU/memory/disk needs)
- 6. Choose the storage location for your instance, this can be either "Ephemeral Drive" or "Cinder Volume". If you choose "Cinder Volume", you will need to add additional configuration
- 7. Choose which processes should be run for any instances that are spawned from this Node Group Template
- 8. Click on the "Create" button to finish creating your Node Group Template

## 2.7.4 Create a Cluster Template

- 1. Navigate to the "Project" dashboard, then the "Data Processing" tab, then click on the "Cluster Templates" panel
- 2. From that page, click on the "Create Template" button at the top right
- 3. Choose your desired Plugin name and Version from the dropdowns and click "Create"
- 4. Under the "Details" tab, you must give your template a name
- 5. Under the "Node Groups" tab, you should add one or more nodes that can be based on one or more templates
- To do this, start by choosing a Node Group Template from the dropdown and click the "+" button
- You can adjust the number of nodes to be spawned for this node group via the text box or the "-" and "+" buttons
- Repeat these steps if you need nodes from additional node group templates
- 6. Optionally, you can adjust your configuration further by using the "General Parameters", "HDFS Parameters" and "MapReduce Parameters" tabs
- 7. Click on the "Create" button to finish creating your Cluster Template

## 2.7.5 Launching a Cluster

- 1. Navigate to the "Project" dashboard, then the "Data Processing" tab, then click on the "Clusters" panel
- 2. Click on the "Launch Cluster" button at the top right
- 3. Choose your desired Plugin name and Version from the dropdowns and click "Create"
- 4. Give your cluster a name (required)
- 5. Choose which cluster template should be used for your cluster
- 6. Choose the image that should be used for your cluster (if you do not see any options here, see Registering an Image above)
- 7. Optionally choose a keypair that can be used to authenticate to your cluster instances
- 8. Click on the "Create" button to start your cluster
- Your cluster's status will display on the Clusters table
- It will likely take several minutes to reach the "Active" state

## 2.7.6 Scaling a Cluster

- 1. From the Data Processing/Clusters page, click on the "Scale Cluster" button of the row that contains the cluster that you want to scale
- 2. You can adjust the numbers of instances for existing Node Group Templates
- 3. You can also add a new Node Group Template and choose a number of instances to launch
- This can be done by selecting your desired Node Group Template from the dropdown and clicking the "+" button
- Your new Node Group will appear below and you can adjust the number of instances via the text box or the "+" and "-" buttons
- 4. To confirm the scaling settings and trigger the spawning/deletion of instances, click on "Scale"

## 2.7.7 Elastic Data Processing (EDP)

#### 2.7.8 Data Sources

Data Sources are where the input and output from your jobs are housed.

- 1. From the Data Processing/Data Sources page, click on the "Create Data Source" button at the top right
- 2. Give your Data Source a name
- 3. Enter the URL of the Data Source
- For a Swift object, enter <container>/<path> (ie: mycontainer/inputfile). Sahara will prepend swift:// for you
- For an HDFS object, enter an absolute path, a relative path or a full URL:
  - /my/absolute/path indicates an absolute path in the cluster HDFS
  - my/path indicates the path /user/hadoop/my/path in the cluster HDFS assuming the defined HDFS user is hadoop
  - hdfs://host:port/path can be used to indicate any HDFS location

- 4. Enter the username and password for the Data Source (also see Additional Notes)
- 5. Enter an optional description
- 6. Click on "Create"
- 7. Repeat for additional Data Sources

#### 2.7.9 Job Binaries

Job Binaries are where you define/upload the source code (mains and libraries) for your job.

- 1. From the Data Processing/Job Binaries page, click on the "Create Job Binary" button at the top right
- 2. Give your Job Binary a name (this can be different than the actual filename)
- 3. Choose the type of storage for your Job Binary
- For "Swift", enter the URL of your binary (<container>/<path>) as well as the username and password (also see Additional Notes)
- For "Internal database", you can choose from "Create a script" or "Upload a new file"
- 4. Enter an optional description
- 5. Click on "Create"
- 6. Repeat for additional Job Binaries

## 2.7.10 Job Templates (Known as "Jobs" in the API)

Job templates are where you define the type of job you'd like to run as well as which "Job Binaries" are required.

- 1. From the Data Processing/Jobs page, click on the "Create Job Template" button at the top right
- 2. Give your Job Template a name
- 3. Choose the type of job you'd like to run
- 4. Choose the main binary from the dropdown
  - · This is required for Hive, Pig, and Spark jobs
  - · Other job types do not use a main binary
- 5. Enter an optional description for your Job Template
- 6. Click on the "Libs" tab and choose any libraries needed by your job template
  - · MapReduce and Java jobs require at least one library
  - Other job types may optionally use libraries
- 7. Click on "Create"

## 2.7.11 Jobs (Known as "Job Executions" in the API)

Jobs are what you get by "Launching" a job template. You can monitor the status of your job to see when it has completed its run

1. From the Data Processing/Job Templates page, find the row that contains the job template you want to launch and click either "Launch on New Cluster" or "Launch on Existing Cluster" the right side of that row

- 2. Choose the cluster (already running–see Launching a Cluster above) on which you would like the job to run
- 3. Choose the Input and Output Data Sources (Data Sources defined above)
- 4. If additional configuration is required, click on the "Configure" tab
- Additional configuration properties can be defined by clicking on the "Add" button
- An example configuration entry might be mapred.mapper.class for the Name and org.apache.oozie.example.SampleMapper for the Value
- 5. Click on "Launch". To monitor the status of your job, you can navigate to the Data Processing/Jobs panel
- 6. You can relaunch a Job from the Jobs page by using the "Relaunch on New Cluster" or "Relaunch on Existing Cluster" links
- Relaunch on New Cluster will take you through the forms to start a new cluster before letting you specify input/output Data Sources and job configuration
- Relaunch on Existing Cluster will prompt you for input/output Data Sources as well as allow you to change job configuration before launching the job

## 2.7.12 Example Jobs

There are sample jobs located in the Sahara repository. In this section, we will give a walkthrough on how to run those jobs via the Horizon UI. These steps assume that you already have a cluster up and running (in the "Active" state).

- Sample Pig job https://github.com/openstack/sahara/tree/master/etc/edp-examples/edp-pig/trim-spaces
- Load the input data file from https://github.com/openstack/sahara/tree/master/etc/edp-examples/edp-pig/trim-spaces/data/input into swift
  - Click on Project/Object Store/Containers and create a container with any name ("samplecontainer" for our purposes here)
  - Click on Upload Object and give the object a name ("piginput" in this case)
- Navigate to Data Processing/Data Sources, Click on Create Data Source
  - Name your Data Source ("pig-input-ds" in this sample)
  - Type = Swift, URL samplecontainer/piginput, fill-in the Source username/password fields with your username/password and click "Create"
- Create another Data Source to use as output for the job
  - Name = pig-output-ds, Type = Swift, URL = samplecontainer/pigoutput, Source username/password, "Create"
- Store your Job Binaries in the Sahara database
  - Navigate to Data Processing/Job Binaries, Click on Create Job Binary
  - Name = example.pig, Storage type = Internal database, click Browse and find example.pig wherever you checked out the sahara project <sahara root>/etc/edp-examples/edp-pig/trim-spaces
  - Create another Job Binary: Name = udf.jar, Storage type = Internal database, click Browse and find udf.jar
     wherever you checked out the sahara project <sahara root>/etc/edp-examples/edp-pig/trim-spaces
- Create a Job Template
  - Navigate to Data Processing/Job Templates, Click on Create Job Template
  - Name = pigsample, Job Type = Pig, Choose "example.pig" as the main binary

- Click on the "Libs" tab and choose "udf.jar", then hit the "Choose" button beneath the dropdown, then click on "Create"
- · Launch your job
  - To launch your job from the Job Templates page, click on the down arrow at the far right of the screen and choose "Launch on Existing Cluster"
  - For the input, choose "pig-input-ds", for output choose "pig-output-ds". Also choose whichever cluster you'd like to run the job on
  - For this job, no additional configuration is necessary, so you can just click on "Launch"
  - You will be taken to the "Jobs" page where you can see your job progress through "PENDING, RUNNING, SUCCEEDED" phases
  - When your job finishes with "SUCCEEDED", you can navigate back to Object Store/Containers and browse to the samplecontainer to see your output. It should be in the "pigoutput" folder
- 2. Sample Spark job https://github.com/openstack/sahara/tree/master/etc/edp-examples/edp-spark
- · Store the Job Binary in the Sahara database
  - Navigate to Data Processing/Job Binaries, Click on Create Job Binary
  - Name = sparkexample.jar, Storage type = Internal database, Browse to the location <sahara root>/etc/edp-examples/edp-spark and choose spark-example.jar, Click "Create"
- Create a Job Template
  - Name = sparkexamplejob, Job Type = Spark, Main binary = Choose sparkexample.jar, Click "Create"
- · Launch your job
  - To launch your job from the Job Templates page, click on the down arrow at the far right of the screen and choose "Launch on Existing Cluster"
  - Choose whichever cluster you'd like to run the job on
  - Click on the "Configure" tab
  - Set the main class to be: org.apache.spark.examples.SparkPi
  - Under Arguments, click Add and fill in the number of "Slices" you want to use for the job. For this example, let's use 100 as the value
  - Click on Launch
  - You will be taken to the "Jobs" page where you can see your job progress through "PENDING, RUNNING, SUCCEEDED" phases
  - When your job finishes with "SUCCEEDED", you can see your results by sshing to the Spark "master" node
  - The output is located at /tmp/spark-edp/<name of job template>/<job id>. You can do cat stdout which should display something like "Pi is roughly 3.14156132"
  - It should be noted that for more complex jobs, the input/output may be elsewhere. This particular job just writes to stdout, which is logged in the folder under /tmp

#### 2.7.13 Additional Notes

1. Throughout the Sahara UI, you will find that if you try to delete an object that you will not be able to delete it if another object depends on it. An example of this would be trying to delete a Job Template that has an existing Job. In order to be able to delete that job, you would first need to delete any Job Templates that relate to that job.

2. In the examples above, we mention adding your username/password for the Swift Data Sources. It should be noted that it is possible to configure Sahara such that the username/password credentials are *not* required. For more information on that, please refer to: *Sahara Advanced Configuration Guide* 

## 2.7.14 Launching a cluster via the Cluster Creation Guide

- 1. Under the Data Processing group, choose "Guides" and then click on the "Cluster Creation Guide" button.
- 2. Click on the "Choose Plugin" button then select the cluster type from the Plugin Name dropdown and choose your target version. When done, click on "Select" to proceed.
- 3. Click on "Create a Master Node Group Template". Give your template a name, choose a flavor and choose which processes should run on nodes launched for this node group. The processes chosen here should be things that are more server-like in nature (namenode, oozieserver, spark master, etc). Optionally, you can set other options here such as availability zone, storage, security and process specific parameters. Click on "Create" to proceed.
- 4. Click on "Create a Worker Node Group Template". Give your template a name, choose a flavor and choose which processes should run on nodes launched for this node group. Processes chosen here should be more worker-like in nature (datanode, spark slave, task tracker, etc). Optionally, you can set other options here such as availability zone, storage, security and process specific parameters. Click on "Create" to proceed.
- 5. Click on "Create a Cluster Template". Give your template a name. Next, click on the "Node Groups" tab and enter the count for each of the node groups (these are pre-populated from steps 3 and 4). It would be common to have 1 for the "master" node group type and some larger number of "worker" instances depending on you desired cluster size. Optionally, you can also set additional parameters for cluster-wide settings via the other tabs on this page. Click on "Create" to proceed.
- 6. Click on "Launch a Cluster". Give your cluster a name and choose the image that you want to use for all instances in your cluster. The cluster template that you created in step 5 is already pre-populated. If you want ssh access to the instances of your cluster, select a keypair from the dropdown. Click on "Launch" to proceed. You will be taken to the Clusters panel where you can see your cluster progress toward the Active state.

## 2.7.15 Running a job via the Job Execution Guide

- 1. Under the Data Processing group, choose "Guides" and then click on the "Job Execution Guide" button.
- 2. Click on "Select type" and choose the type of job that you want to run.
- 3. If your job requires input/output data sources, you will have the option to create them via the "Create a Data Source" button (Note: This button will not be shown for job types that do not require data sources). Give your data source a name and choose the type. If you have chosen swift, you may also enter the username and password. Enter the URL for your data source. For more details on what the URL should look like, see Data Sources.
- 4. Click on "Create a job template". Give your job template a name. Depending on the type of job that you've chosen, you may need to select your main binary and/or additional libraries (available from the "Libs" tab). If you have not yet uploaded the files to run your program, you can add them via the "+" icon next to the "Choose a main binary" select box.
- 5. Click on "Launch job". Choose the active cluster where you want to run you job. Optionally, you can click on the "Configure" tab and provide any required configuration, arguments or parameters for your job. Click on "Launch" to execute your job. You will be taken to the Jobs panel where you can monitor the state of your job as it progresses.

## 2.8 Features Overview

This page highlights some of the most prominent features available in sahara. The guidance provided here is primarily focused on the runtime aspects of sahara, for discussions about configuring the sahara server processes please see the *Sahara Configuration Guide* and *Sahara Advanced Configuration Guide*.

## 2.8.1 Anti-affinity

One of the problems with running data processing applications on OpenStack is the inability to control where an instance is actually running. It is not always possible to ensure that two new virtual machines are started on different physical machines. As a result, any replication within the cluster is not reliable because all replicas may turn up on one physical machine. To remedy this, sahara provides the anti-affinity feature to explicitly command all instances of the specified processes to spawn on different Compute nodes. This is especially useful for Hadoop data node processes to increase HDFS replica reliability.

Starting with the Juno release, sahara can create server groups with the anti-affinity policy to enable this feature. Sahara creates one server group per cluster and assigns all instances with affected processes to this server group. Refer to the Nova documentation on how server groups work.

This feature is supported by all plugins out of the box, and can be enabled during the cluster template creation.

## 2.8.2 Block Storage support

OpenStack Block Storage (cinder) can be used as an alternative for ephemeral drives on instances. Using Block Storage volumes increases the reliability of data which is important for HDFS service.

A user can set how many volumes will be attached to each instance in a node group, and the size of each volume.

All volumes are attached during cluster creation/scaling operations.

### 2.8.3 Cluster scaling

Cluster scaling allows users to change the number of running instances in a cluster without needing to recreate the cluster. Users may increase or decrease the number of instances in node groups or add new node groups to existing clusters.

If a cluster fails to scale properly, all changes will be rolled back.

## 2.8.4 Data-locality

It is extremely important for data processing applications to perform work locally on the same rack, OpenStack Compute node, or virtual machine. Hadoop supports a data-locality feature and can schedule jobs to task tracker nodes that are local for the input stream. In this manner the task tracker nodes can communicate directly with the local data nodes.

Sahara supports topology configuration for HDFS and Object Storage data sources. For more information on configuring this option please see the *Data-locality configuration* documentation.

#### 2.8.5 Distributed Mode

The Sahara Installation Guide suggests launching sahara as a single sahara-all process. It is also possible to run sahara in distributed mode with sahara-api and sahara-engine processes running on several machines

simultaneously. Running in distributed mode allows sahara to offload intensive tasks to the engine processes while keeping the API process free to handle requests.

For an expanded discussion of configuring sahara to run in distributed mode please see the *Distributed mode configuration* documentation.

## 2.8.6 Hadoop HDFS High Availability

Hadoop HDFS High Availability (HDFS HA) provides an architecture to ensure that HDFS will continue to work in the result of an active namenode failure. It uses 2 namenodes in an active/standby configuration to provide this availability.

High availability is achieved by using a set of journalnodes and Zookeeper servers along with ZooKeeper Failover Controllers (ZKFC) and additional configuration changes to HDFS and other services that use HDFS.

Currently HDFS HA is only supported with the HDP 2.0.6 plugin. The feature is enabled through a cluster\_configs parameter in the cluster's JSON:

## 2.8.7 Networking support

Sahara supports both the nova-network and neutron implementations of OpenStack Networking. By default sahara is configured to behave as if the nova-network implementation is available. For OpenStack installations that are using the neutron project please see *Networking configuration*.

## 2.8.8 Object Storage support

Sahara can use OpenStack Object Storage (swift) to store job binaries and data sources utilized by its job executions and clusters. In order to leverage this support within Hadoop, including using Object Storage for data sources for EDP, Hadoop requires the application of a patch. For additional information about enabling this support, including patching Hadoop and configuring sahara, please refer to the *Swift Integration* documentation.

## 2.8.9 Orchestration support

Sahara may use the OpenStack Orchestration engine (heat) to provision nodes for clusters. For more information about enabling Orchestration usage in sahara please see *Orchestration configuration*.

## 2.8.10 Plugin Capabilities

The following table provides a plugin capability matrix:

Feature	Plugin			
	Vanilla	HDP	Cloudera	Spark
Nova and Neutron network	X	X	X	X
Cluster Scaling	X	Scale Up	x	X
Swift Integration	X	X	x	N/A
Cinder Support	X	X	x	X
Data Locality	X	X	N/A	X
EDP	X	X	x	X

## 2.8.11 Security group management

Sahara allows you to control which security groups will be used for created instances. This can be done by providing the security\_groups parameter for the node group or node group template. The default for this option is an empty list, which will result in the default project security group being used for the instances.

Sahara may also create a security group for instances in the node group automatically. This security group will only contain open ports for required instance processes and the sahara engine. This option is useful for development and for when your installation is secured from outside environments. For production environments we recommend controlling the security group policy manually.

## 2.8.12 Volume-to-instance locality

Having an instance and an attached volume on the same physical host can be very helpful in order to achieve high-performance disk I/O operations. To achieve this, sahara provides access to the Block Storage volume intance locality functionality.

For more information on using volume instance locality with sahara, please see the *Volume instance locality configu*ration documentation.

## 2.9 Registering an Image

Sahara deploys a cluster of machines based on images stored in Glance. Each plugin has its own requirements on image contents, see specific plugin documentation for details. A general requirement for an image is to have the cloud-init package installed.

Sahara requires the image to be registered in the Sahara Image Registry in order to work with it. A registered image must have two properties set:

- username a name of the default cloud-init user.
- tags certain tags mark image to be suitable for certain plugins.

The username depends on the image that is used and tags depend on the plugin used. You can find both in the respective plugin's documentation.

#### **Plugins**

## 2.10 Provisioning Plugins

This page lists all available provisioning plugins. In general a plugin enables Sahara to deploy a specific data intensive application (Hadoop, Spark) distribution in various topologies and with management/monitoring tools.

Vanilla Plugin - deploys Vanilla Apache Hadoop

- Hortonworks Data Platform Plugin deploys Hortonworks Data Platform
- Spark Plugin deploys Apache Spark with Cloudera HDFS
- MapR Distribution Plugin deploys MapR plugin with MapR File System
- Cloudera Plugin deploys Cloudera Hadoop

# 2.11 Vanilla Plugin

The vanilla plugin is a reference implementation which allows users to operate a cluster with Apache Hadoop.

For cluster provisioning prepared images should be used. They already have Apache Hadoop 1.2.1 and Apache Hadoop 2.6.0 installed.

You may build images by yourself using *Building Images for Vanilla Plugin* or you could download prepared images from http://sahara-files.mirantis.com/images/upstream/kilo/

Keep in mind that if you want to use the Swift Integration feature ( *Features Overview*), Hadoop 1.2.1 must be patched with an implementation of Swift File System. For more information about patching required by the Swift Integration feature see *Swift Integration*.

Vanilla plugin requires an image to be tagged in Sahara Image Registry with two tags: 'vanilla' and '<hadoop version>' (e.g. '1.2.1').

The default username specified for these images is different for each distribution:

OS	username	
Ubuntu 14.04	ubuntu	
Fedora 20	fedora	
CentOS 6.5	cloud-user	

Known issue:

Hive job has "KILLED" state after scaling cluster: https://bugs.launchpad.net/sahara/+bug/1413602

### 2.11.1 Cluster Validation

When user creates or scales a Hadoop cluster using a Vanilla plugin, the cluster topology requested by user is verified for consistency.

Currently there are the following limitations in cluster topology for Vanilla plugin:

For Vanilla Hadoop version 1.X.X:

- · Cluster must contain exactly one namenode
- · Cluster can contain at most one jobtracker
- Cluster can contain at most one oozie and this process is also required for EDP
- Cluster can't contain oozie without jobtracker
- Cluster can't have tasktracker nodes if it doesn't have jobtracker
- Cluster can't have hive node if it doesn't have jobtracker.
- Cluster can have at most one hive node.

For Vanilla Hadoop version 2.X.X:

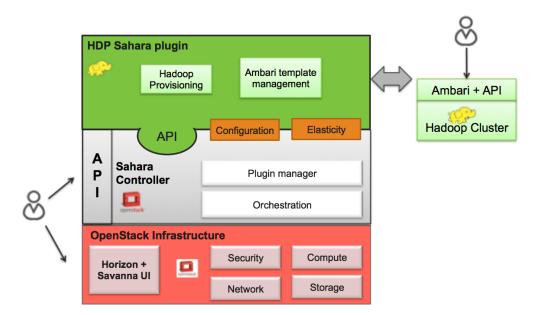

Cluster must contain exactly one namenode

2.11. Vanilla Plugin 33

- Cluster can contain at most one resourcemanager
- Cluster can contain at most one historyserver
- Cluster can contain at most one oozie and this process is also required for EDP
- Cluster can't contain oozie without resourcemanager and without historyserver
- Cluster can't have nodemanager nodes if it doesn't have resourcemanager
- Cluster can have at most one hiveserver node.

# 2.12 Hortonworks Data Platform Plugin

The Hortonworks Data Platform (HDP) Sahara plugin provides a way to provision HDP clusters on OpenStack using templates in a single click and in an easily repeatable fashion. As seen from the architecture diagram below, the Sahara controller serves as the glue between Hadoop and OpenStack. The HDP plugin mediates between the Sahara controller and Apache Ambari in order to deploy and configure Hadoop on OpenStack. Core to the HDP Plugin is Apache Ambari which is used as the orchestrator for deploying HDP on OpenStack.

The HDP plugin can make use of Ambari Blueprints for cluster provisioning.

# 2.12.1 Apache Ambari Blueprints

Apache Ambari Blueprints is a portable document definition, which provides a complete definition for an Apache Hadoop cluster, including cluster topology, components, services and their configurations. Ambari Blueprints can be consumed by the HDP plugin to instantiate a Hadoop cluster on OpenStack. The benefits of this approach is that it allows for Hadoop clusters to be configured and deployed using an Ambari native format that can be used with as well as outside of OpenStack allowing for clusters to be re-instantiated in a variety of environments.

For more information about Apache Ambari Blueprints, refer to: https://issues.apache.org/jira/browse/AMBARI-1783. Note that Apache Ambari Blueprints are not yet finalized.

## 2.12.2 Operation

The HDP Plugin performs the following four primary functions during cluster creation:

- 1. Software deployment the plugin orchestrates the deployment of the required software to the target VMs
- 2. Services Installation the Hadoop services configured for the node groups within the cluster are installed on the associated VMs
- 3. Services Configuration the plugin merges the default configuration values and user provided configurations for each installed service to the cluster
- 4. Services Start the plugin invokes the appropriate APIs to indicate to the Ambari Server that the cluster services should be started

## 2.12.3 Images

The Sahara HDP plugin can make use of either minimal (operating system only) images or pre-populated HDP images. The base requirement for both is that the image is cloud-init enabled and contains a supported operating system (see <a href="http://docs.hortonworks.com/HDPDocuments/HDP1/HDP-1.2.4/bk\_hdp1-system-admin-guide/content/sysadminguides\_ha\_chap2\_3.html">http://docs.hortonworks.com/HDPDocuments/HDP1/HDP-1.2.4/bk\_hdp1-system-admin-guide/content/sysadminguides\_ha\_chap2\_3.html</a>).

The advantage of a pre-populated image is that provisioning time is reduced, as packages do not need to be downloaded and installed which make up the majority of the time spent in the provisioning cycle. In addition, provisioning large clusters will put a burden on the network as packages for all nodes need to be downloaded from the package repository.

For more information about HDP images, refer to https://github.com/openstack/sahara-image-elements.

There are three VM images provided for use with the HDP Plugin, that can also be built using the tools available in sahara-image-elemnts:

- sahara-juno-hdp-1.3.2-centos-6.5.qcow2: This image contains most of the requisite packages necessary for HDP deployment. The packages contained herein correspond to the HDP 1.3 release. The operating system is a minimal CentOS 6.5 cloud-init enabled install. This image can only be used to provision HDP 1.3 hadoop clusters.
- sahara-juno-hdp-2.0.6-centos-6.5.qcow2: This image contains most of the requisite packages necessary for HDP deployment. The packages contained herein correspond to the HDP 2.0.6 release. The operating system is a minimal CentOS 6.5 cloud-init enabled install. This image can only be used to provision HDP 2.0.6 hadoop clusters.
- 3. sahara-juno-hdp-plain-centos-6.5.qcow2: This image provides only a minimal install of CentOS 6.5 and is cloud-init enabled. This image can be used to provision any versions of HDP supported by Sahara.

You could download well tested and up-to-date prepared images from http://sahara-files.mirantis.com/images/upstream/kilo/

HDP plugin requires an image to be tagged in Sahara Image Registry with two tags: 'hdp' and '<hdp version>' (e.g. '1.3.2').

Also in the Image Registry you will need to specify username for an image. The username specified should be 'cloud-user'.

# 2.12.4 HDFS NameNode High Availability

HDFS NameNode High Availability (Using the Quorum Journal Manager) can be deployed automatically with HDP 2.0.6. Currently the only way to deploy it is through the command line client (python-saharaclient) or Sahara REST API by simply adding the following cluster\_configs parameter in the cluster's JSON:

Support for deploying the NameNode High Availability through Sahara Dashboard will be added in the future.

The NameNode High Availability is deployed using 2 NameNodes, one active and one standby. The NameNodes use a set of JOURNALNODES and ZOOKEEPER\_SERVERS to ensure the necessary synchronization.

A typical Highly available HDP 2.0.6 cluster uses 2 separate NameNodes, at least 3 JOURNALNODES and at least 3 ZOOKEEPER\_SERVERS.

When HDFS NameNode High Availability is enabled, the plugin will perform the following additional validations:

- Ensure the existence of 2 NAMENODES processes in the cluster
- Ensure the existence of at least 3 JOURNALNODES processes in the cluster
- Ensure the existence of at least 3 ZOOKEEPER\_SERVERS processes in the cluster

### 2.12.5 Limitations

The HDP plugin currently has the following limitations:

• It is not possible to decrement the number of node-groups or hosts per node group in a Sahara generated cluster.

## 2.12.6 HDP Version Support

The HDP plugin currently supports HDP 1.3.2 and HDP 2.0.6. Support for future version of HDP will be provided shortly after software is generally available.

### 2.12.7 Cluster Validation

Prior to Hadoop cluster creation, the HDP plugin will perform the following validation checks to ensure a successful Hadoop deployment:

- Ensure the existence of a NAMENODE process in the cluster
- Ensure the existence of a JOBTRACKER should any TASKTRACKER be deployed to the cluster
- Ensure the deployment of one Ambari Server instance to the cluster
- Ensure that each defined node group had an associated Ambari Agent configured

## 2.12.8 The HDP Plugin and Sahara Support

For more information, please contact Hortonworks.

# 2.13 Spark Plugin

The Spark Sahara plugin provides a way to provision Apache Spark clusters on OpenStack in a single click and in an easily repeatable fashion.

Currently Spark is installed in standalone mode, with no YARN or Mesos support.

# 2.13.1 Images

For cluster provisioning prepared images should be used. The Spark plugin has been developed and tested with the images generated by the *Building Images for Vanilla Plugin*. Those Ubuntu images already have Cloudera CDH4 HDFS and Apache Spark installed. A prepared image can be found at the following location:

• http://sahara-files.mirantis.com/sahara-juno-spark-1.0.0-ubuntu-14.04.qcow2

The Spark plugin requires an image to be tagged in Sahara Image Registry with two tags: 'spark' and '<Spark version>' (e.g. '1.0.0').

Also you should specify the username of the default cloud-user used in the image. For images generated with the DIB it is 'ubuntu'.

Note that the Spark cluster is deployed using the scripts available in the Spark distribution, which allow to start all services (master and slaves), stop all services and so on. As such (and as opposed to CDH HDFS daemons), Spark is not deployed as a standard Ubuntu service and if the virtual machines are rebooted, Spark will not be restarted.

## 2.13.2 Spark configuration

Spark needs few parameters to work and has sensible defaults. If needed they can be changed when creating the Sahara cluster template. No node group options are available.

Once the cluster is ready, connect with ssh to the master using the 'ubuntu' user and the appropriate ssh key. Spark is installed in /opt/spark and should be completely configured and ready to start executing jobs. At the bottom of the cluster information page from the OpenStack dashboard, a link to the Spark web interface is provided.

### 2.13.3 Cluster Validation

When a user creates an Hadoop cluster using the Spark plugin, the cluster topology requested by user is verified for consistency.

Currently there are the following limitations in cluster topology for the Spark plugin:

- Cluster must contain exactly one HDFS namenode
- Cluster must contain exactly one Spark master
- · Cluster must contain at least one Spark slave
- Cluster must contain at least one HDFS datanode

The tested configuration puts the NameNode co-located with the master and a DataNode with each slave to maximize data locality.

### 2.13.4 Limitations

Swift support is not available in Spark. Once it is developed there, it will be possible to add it to this plugin.

2.13. Spark Plugin 37

# 2.14 Cloudera Plugin

The Cloudera plugin is a Sahara plugin which allows the user to deploy and operate a cluster with Cloudera Manager.

The Cloudera plugin is enabled in Sahara by default. You can manually modify the Sahara configuration file (default /etc/sahara/sahara.conf) to explicitly enable or disable it in "plugins" line.

You need to build images using *Building Images for Cloudera Plugin* to produce images used to provision cluster or you could download prepared images from http://sahara-files.mirantis.com/images/upstream/kilo/ They already have Cloudera Express installed (5.0.0 or 5.3.0 version).

The cloudera plugin requires an image to be tagged in Sahara Image Registry with two tags: 'cdh' and '<cloudera version>' (e.g. '5' or '5.3.0').

The default username specified for these images is different for each distribution:

OS	username
Ubuntu 12.04	ubuntu
CentOS 6.5	cloud-user

## 2.14.1 Services Supported

Currently below services are supported in both versions of Cloudera plugin: HDFS, Oozie, YARN, Spark, Zookeeper, Hive, Hue, HBase. 5.3.0 version of Cloudera Plugin also supported following services: Impala, Flume, Solr, Sqoop, and Key-value Store Indexer.

**Note:** Sentry service is enabled in Cloudera plugin. However, for we do not enable Kerberos authentication in the cluster, which is required for Sentry functionality, using Sentry service will not really take any effect, and other services depending on Sentry will not do any authentication too.

#### 2.14.2 Cluster Validation

When the user performs an operation on the cluster using a Cloudera plugin, the cluster topology requested by the user is verified for consistency.

The following limitations are required in the cluster topology for the both cloudera plugin versions:

- Cluster must contain exactly one manager.
- Cluster must contain exactly one namenode.
- Cluster must contain exactly one secondarynamenode.
- Cluster can contain at most one resourcemanager and this process is also required by nodemanager.
- Cluster can contain at most one jobhistory and this process is also required for resourcemanager.
- Cluster can contain at most one oozie and this process is also required for EDP.
- Cluster can't contain oozie without datanode.
- Cluster can't contain oozie without nodemanager.
- Cluster can't contain oozie without jobhistory.
- Cluster can't contain hive on the cluster without the following services: metastore, hive server, webcat and resourcemanager.
- · Cluster can contain at most one hue server.

- Cluster can't contain hue server without hive service and oozie.
- Cluster can contain at most one spark history server.
- Cluster can't contain spark history server without resourcemanager.
- Cluster can't contain hbase master service without at least one zookeeper and at least one hbase regionserver.
- Cluster can't contain hbase regionserver without at least one hbase maser.

In case of 5.3.0 version of Cloudera Plugin there are few extra limitations in the cluster topology:

- Cluster can't contain flume without at least one datanode.
- Cluster can contain at most one sentry server service.
- Cluster can't contain sentry server service without at least one zookeeper and at least one datanode.
- Cluster can't contain solr server without at least one zookeeper and at least one datanode.
- Cluster can contain at most one sqoop server.
- Cluster can't contain sqoop server without at least one datanode, nodemanager and jobhistory.
- Cluster can't contain hbase indexer without at least one datanode, zookeeper, solr server and hbase master.
- Cluster can contain at most one impala catalog server.
- Cluster can contain at most one impala statestore.
- Cluster can't contain impala catalogserver without impala statestore, at least one impalad service, at least one datanode, and metastore.

# 2.15 MapR Distribution Plugin

The MapR Sahara plugin allows to provision MapR clusters on OpenStack in an easy way and do it, quickly, conveniently and simply.

# 2.15.1 Operation

The MapR Plugin performs the following four primary functions during cluster creation:

- 1. MapR components deployment the plugin manages the deployment of the required software to the target VMs
- 2. Services Installation MapR services are installed according to provided roles list
- 3. Services Configuration the plugin combines default settings with user provided settings
- 4. Services Start the plugin starts appropriate services according to specified roles

## 2.15.2 Images

The Sahara MapR plugin can make use of either minimal (operating system only) images or pre-populated MapR images. The base requirement for both is that the image is cloud-init enabled and contains a supported operating system (see http://doc.mapr.com/display/MapR/OS+Support+Matrix).

The advantage of a pre-populated image is that provisioning time is reduced, as packages do not need to be downloaded which make up the majority of the time spent in the provisioning cycle. In addition, provisioning large clusters will put a burden on the network as packages for all nodes need to be downloaded from the package repository.

For more information about MapR images, refer to https://github.com/openstack/sahara-image-elements.

There are eight VM images provided for use with the MapR Plugin, that can also be built using the tools available in sahara-image-elements:

- https://s3-us-west-2.amazonaws.com/sahara-images/ubuntu\_trusty\_mapr\_plain\_latest.qcow2
- https://s3-us-west-2.amazonaws.com/sahara-images/centos\_6.5\_mapr\_plain\_latest.qcow2
- https://s3-us-west-2.amazonaws.com/sahara-images/ubuntu\_trusty\_mapr\_3.1.1\_latest.qcow2
- https://s3-us-west-2.amazonaws.com/sahara-images/centos\_6.5\_mapr\_3.1.1\_latest.qcow2
- https://s3-us-west-2.amazonaws.com/sahara-images/ubuntu\_trusty\_mapr\_4.0.1\_latest.qcow2
- https://s3-us-west-2.amazonaws.com/sahara-images/centos\_6.5\_mapr\_4.0.1\_latest.qcow2
- https://s3-us-west-2.amazonaws.com/sahara-images/ubuntu\_trusty\_mapr\_4.0.2\_latest.qcow2
- https://s3-us-west-2.amazonaws.com/sahara-images/centos\_6.5\_mapr\_4.0.2\_latest.qcow2

MapR plugin needs an image to be tagged in Sahara Image Registry with two tags: 'mapr' and '<MapR version>' (e.g. '4.0.1.mrv2').

Note that Spark should be run on plain or 4.0.1 images.

The default username specified for these images is different for each distribution:

OS	username	
Ubuntu 14.04	ubuntu	
CentOS 6.5	cloud-user	

## 2.15.3 Hadoop Version Support

The MapR plugin currently supports Hadoop 0.20.2 (3.1.1, 4.0.1.mrv1, 4.0.2.mrv1), Hadoop 2.4.1 (4.0.2.mrv2) and Hadoop 2.5.1 (4.0.2.mrv2).

### 2.15.4 Cluster Validation

When the user creates or scales a Hadoop cluster using a mapr plugin, the cluster topology requested by the user is verified for consistency.

Every MapR cluster must contain:

- at least 1 *CLDB* process
- exactly 1 Webserver process
- odd number of ZooKeeper processes but not less than 1
- FileServer process on every node
- at least 1 Cinder volume or ephemeral drive per instance

Every Hadoop cluster must contain exactly 1 *Oozie* process

Every MapReduce v1 cluster must contain:

- at least 1 JobTracker process
- at least 1 *TaskTracker* process

Every MapReduce v2 cluster must contain:

- exactly 1 ResourceManager process
- exactly 1 HistoryServer process

• at least 1 NodeManager process

Every Spark cluster must contain:

- exactly 1 Spark Master process
- exactly 1 Spark HistoryServer process
- at least 1 Spark Slave (worker) process

HBase service is considered valid if:

- cluster has at least 1 HBase-Master process
- cluster has at least 1 HBase-RegionServer process

Hive service is considered valid if:

- cluster has exactly 1 HiveMetastore process
- cluster has exactly 1 HiveServer2 process

Hue service is considered valid if:

- cluster has exactly 1 Hue process
- Hue process resides on the same node as HttpFS process

HttpFS service is considered valid if cluster has exactly 1 HttpFS process

Sqoop service is considered valid if cluster has exactly 1 Sqoop2-Server process

## 2.15.5 The MapR Plugin

For more information, please contact MapR.

**Elastic Data Processing** 

# 2.16 Elastic Data Processing (EDP)

### 2.16.1 Overview

Sahara's Elastic Data Processing facility or *EDP* allows the execution of jobs on clusters created from Sahara. EDP supports:

- Hive, Pig, MapReduce, MapReduce.Streaming, Java, and Shell job types on Hadoop clusters
- Spark jobs on Spark standalone clusters and MapR spark clusters
- storage of job binaries in Swift or Sahara's own database
- · access to input and output data sources in
  - HDFS for all job types
  - Swift for all types excluding Hive
- configuration of jobs at submission time
- execution of jobs on existing clusters or transient clusters

### 2.16.2 Interfaces

The EDP features can be used from the Sahara web UI which is described in the Sahara (Data Processing) UI User Guide.

The EDP features also can be used directly by a client through the REST api

## 2.16.3 EDP Concepts

Sahara EDP uses a collection of simple objects to define and execute jobs. These objects are stored in the Sahara database when they are created, allowing them to be reused. This modular approach with database persistence allows code and data to be reused across multiple jobs.

The essential components of a job are:

- · executable code to run
- · input data to process
- · an output data location
- · any additional configuration values needed for the job run

These components are supplied through the objects described below.

#### **Job Binaries**

A *Job Binary* object stores a URL to a single script or Jar file and any credentials needed to retrieve the file. The file itself may be stored in the Sahara internal database or in Swift.

Files in the Sahara database are stored as raw bytes in a *Job Binary Internal* object. This object's sole purpose is to store a file for later retrieval. No extra credentials need to be supplied for files stored internally.

Sahara requires credentials (username and password) to access files stored in Swift unless Swift proxy users are configured as described in *Sahara Advanced Configuration Guide*. The Swift service must be running in the same OpenStack installation referenced by Sahara.

There is a configurable limit on the size of a single job binary that may be retrieved by Sahara. This limit is 5MB and may be set with the *job\_binary\_max\_KB* setting in the sahara.conf configuration file.

### **Jobs**

A *Job* object specifies the type of the job and lists all of the individual Job Binary objects that are required for execution. An individual Job Binary may be referenced by multiple Jobs. A Job object specifies a main binary and/or supporting libraries depending on its type:

Job type	Main binary	Libraries
Hive	required	optional
Pig	required	optional
MapReduce	not used	required
MapReduce.Streaming	not used	optional
Java	not used	required
Shell	required	optional
Spark	required	optional

#### **Data Sources**

A *Data Source* object stores a URL which designates the location of input or output data and any credentials needed to access the location.

Sahara supports data sources in Swift. The Swift service must be running in the same OpenStack installation referenced by Sahara.

Sahara also supports data sources in HDFS. Any HDFS instance running on a Sahara cluster in the same OpenStack installation is accessible without manual configuration. Other instances of HDFS may be used as well provided that the URL is resolvable from the node executing the job.

Some job types require the use of data source objects to specify input and output when a job is launched. For example, when running a Pig job the UI will prompt the user for input and output data source objects.

Other job types like Java or Spark do not require the user to specify data sources. For these job types, data paths are passed as arguments. For convenience, Sahara allows data source objects to be referenced by name or id. The section Using Data Source References as Arguments gives further details.

#### **Job Execution**

Job objects must be *launched* or *executed* in order for them to run on the cluster. During job launch, a user specifies execution details including data sources, configuration values, and program arguments. The relevant details will vary by job type. The launch will create a *Job Execution* object in Sahara which is used to monitor and manage the job.

To execute Hadoop jobs, Sahara generates an Oozie workflow and submits it to the Oozie server running on the cluster. Familiarity with Oozie is not necessary for using Sahara but it may be beneficial to the user. A link to the Oozie web console can be found in the Sahara web UI in the cluster details.

For Spark jobs, Sahara uses the *spark-submit* shell script and executes the Spark job from the master node. Logs of spark jobs run by Sahara can be found on the master node under the */tmp/spark-edp* directory.

### 2.16.4 General Workflow

The general workflow for defining and executing a job in Sahara is essentially the same whether using the web UI or the REST API.

- 1. Launch a cluster from Sahara if there is not one already available
- 2. Create all of the Job Binaries needed to run the job, stored in the Sahara database or in Swift
  - When using the REST API and internal storage of job binaries, there is an extra step here to first create the Job Binary Internal objects
  - Once the Job Binary Internal objects are created, Job Binary objects may be created which refer to them by URL
- 3. Create a Job object which references the Job Binaries created in step 2
- 4. Create an input Data Source which points to the data you wish to process
- 5. Create an output Data Source which points to the location for output data
- 6. Create a Job Execution object specifying the cluster and Job object plus relevant data sources, configuration values, and program arguments
  - When using the web UI this is done with the Launch On Existing Cluster or Launch on New Cluster buttons on the Jobs tab
  - When using the REST API this is done via the /jobs/<job\_id>/execute method

The workflow is simpler when using existing objects. For example, to construct a new job which uses existing binaries and input data a user may only need to perform steps 3, 5, and 6 above. Of course, to repeat the same job multiple times a user would need only step 6.

### Specifying Configuration Values, Parameters, and Arguments

Jobs can be configured at launch. The job type determines the kinds of values that may be set:

Job type	Configuration Values	Parameters	Arguments
Hive	Yes	Yes	No
Pig	Yes	Yes	Yes
MapReduce	Yes	No	No
MapReduce.Streaming	Yes	No	No
Java	Yes	No	Yes
Shell	Yes	Yes	Yes
Spark	Yes	No	Yes

- Configuration values are key/value pairs.
  - The EDP configuration values have names beginning with edp. and are consumed by Sahara
  - Other configuration values may be read at runtime by Hadoop jobs
  - Currently additional configuration values are not available to Spark jobs at runtime
- *Parameters* are key/value pairs. They supply values for the Hive and Pig parameter substitution mechanisms. In Shell jobs, they are passed as environment variables.
- Arguments are strings passed as command line arguments to a shell or main program

These values can be set on the *Configure* tab during job launch through the web UI or through the *job\_configs* parameter when using the */jobs/<job\_id>/execute* REST method.

In some cases Sahara generates configuration values or parameters automatically. Values set explicitly by the user during launch will override those generated by Sahara.

## **Using Data Source References as Arguments**

Sometimes it's necessary or desirable to pass a data path as an argument to a job. In these cases, a user may simply type out the path as an argument when launching a job. If the path requires credentials, the user can manually add the credentials as configuration values. However, if a data source object has been created that contains the desired path and credentials there is no need to specify this information manually.

As a convenience, Sahara allows data source objects to be referenced by name or id in arguments, configuration values, or parameters. When the job is executed, Sahara will replace the reference with the path stored in the data source object and will add any necessary credentials to the job configuration. Referencing an existing data source object is much faster than adding this information by hand. This is particularly useful for job types like Java or Spark that do not use data source objects directly.

There are two job configuration parameters that enable data source references. They may be used with any job type and are set on the Configuration tab when the job is launched:

• edp.substitute\_data\_source\_for\_name (default False) If set to True, causes Sahara to look for data source object name references in configuration values, arguments, and parameters when a job is launched. Name references have the form datasource://name of the object.

For example, assume a user has a WordCount application that takes an input path as an argument. If there is a data source object named **my\_input**, a user may simply set the **edp.substitute\_data\_source\_for\_name** configuration parameter to **True** and add **datasource://my input** as an argument when launching the job.

• edp.substitute\_data\_source\_for\_uuid (default False) If set to True, causes Sahara to look for data source object ids in configuration values, arguments, and parameters when a job is launched. A data source object id is a uuid, so they are unique. The id of a data source object is available through the UI or the Sahara command line client. A user may simply use the id as a value.

### **Generation of Swift Properties for Data Sources**

If Swift proxy users are not configured (see *Sahara Advanced Configuration Guide*) and a job is run with data source objects containing Swift paths, Sahara will automatically generate Swift username and password configuration values based on the credentials in the data sources. If the input and output data sources are both in Swift, it is expected that they specify the same credentials.

The Swift credentials may be set explicitly with the following configuration values:

Name	
fs.swift.service.sahara.u	sername
fs.swift.service.sahara.p	assword

Setting the Swift credentials explicitly is required when passing literal Swift paths as arguments instead of using data source references. When possible, use data source references as described in Using Data Source References as Arguments.

### **Additional Details for Hive jobs**

Sahara will automatically generate values for the INPUT and OUTPUT parameters required by Hive based on the specified data sources.

#### Additional Details for Pig jobs

Sahara will automatically generate values for the INPUT and OUTPUT parameters required by Pig based on the specified data sources.

For Pig jobs, arguments should be thought of as command line arguments separated by spaces and passed to the pig shell.

Parameters are a shorthand and are actually translated to the arguments -param name=value

### Additional Details for MapReduce jobs

#### **Important!**

If the job type is MapReduce, the mapper and reducer classes *must* be specified as configuration values. Note, the UI will not prompt the user for these required values, they must be added manually with the Configure tab. Make sure to add these values with the correct names:

Name	Example Value
mapred.mapper.class	org.apache.oozie.example.SampleMapper
mapred.reducer.class	org.apache.oozie.example.SampleReducer

### Additional Details for MapReduce. Streaming jobs

### **Important!**

If the job type is MapReduce. Streaming, the streaming mapper and reducer classes *must* be specified.

In this case, the UI *will* prompt the user to enter mapper and reducer values on the form and will take care of adding them to the job configuration with the appropriate names. If using the python client, however, be certain to add these values to the job configuration manually with the correct names:

Name	Example Value	
edp.streaming.mapper	/bin/cat	
edp.streaming.reducer	/usr/bin/wc	

### Additional Details for Java jobs

Data Source objects are not used directly with Java job types. Instead, any input or output paths must be specified as arguments at job launch either explicitly or by reference as described in Using Data Source References as Arguments. Using data source references is the recommended way to pass paths to Java jobs.

If configuration values are specified, they must be added to the job's Hadoop configuration at runtime. There are two methods of doing this. The simplest way is to use the **edp.java.adapt\_for\_oozie** option described below. The other method is to use the code from this example to explicitly load the values.

The following special configuration values are read by Sahara and affect how Java jobs are run:

• edp.java.main\_class (required) Specifies the full name of the class containing main(String[] args)

A Java job will execute the **main** method of the specified main class. Any arguments set during job launch will be passed to the program through the **args** array.

- oozie.libpath (optional) Specifies configuration values for the Oozie share libs, these libs can be shared by different workflows
- edp. java. java\_opts (optional) Specifies configuration values for the JVM
- edp.java.adapt\_for\_oozie (optional) Specifies that Sahara should perform special handling of configuration values and exit conditions. The default is **False**.

If this configuration value is set to **True**, Sahara will modify the job's Hadoop configuration before invoking the specified **main** method. Any configuration values specified during job launch (excluding those beginning with **edp.**) will be automatically set in the job's Hadoop configuration and will be available through standard methods.

Secondly, setting this option to **True** ensures that Oozie will handle program exit conditions correctly.

At this time, the following special configuration value only applies when running jobs on a cluster generated by the Cloudera plugin with the **Enable Hbase Common Lib** cluster config set to **True** (the default value):

• edp.hbase\_common\_lib (optional) Specifies that a common Hbase lib generated by Sahara in HDFS be added to the oozie.libpath. This for use when an Hbase application is driven from a Java job. Default is False.

The **edp-wordcount** example bundled with Sahara shows how to use configuration values, arguments, and Swift data paths in a Java job type. Note that the example does not use the **edp.java.adapt\_for\_oozie** option but includes the code to load the configuration values explicitly.

### **Additional Details for Shell jobs**

A shell job will execute the script specified as main, and will place any files specified as libs in the same working directory (on both the filesystem and in HDFS). Command line arguments may be passed to the script through the args array, and any params values will be passed as environment variables.

Data Source objects are not used directly with Shell job types but data source references may be used as described in Using Data Source References as Arguments.

The **edp-shell** example bundled with Sahara contains a script which will output the executing user to a file specified by the first command line argument.

### **Additional Details for Spark jobs**

Data Source objects are not used directly with Spark job types. Instead, any input or output paths must be specified as arguments at job launch either explicitly or by reference as described in Using Data Source References as Arguments. Using data source references is the recommended way to pass paths to Spark jobs.

Spark jobs use some special configuration values:

 edp.java.main\_class (required) Specifies the full name of the class containing the Java or Scala main method:

```
main(String[] args) for Javamain(args: Array[String] for Scala
```

A Spark job will execute the **main** method of the specified main class. Any arguments set during job launch will be passed to the program through the **args** array.

• edp.spark.adapt\_for\_swift (optional) If set to **True**, instructs Sahara to modify the job's Hadoop configuration so that Swift paths may be accessed. Without this configuration value, Swift paths will not be accessible to Spark jobs. The default is **False**.

The edp-spark example bundled with Sahara contains a Spark program for estimating Pi.

## 2.16.5 Special Sahara URLs

Sahara uses custom URLs to refer to objects stored in Swift or the Sahara internal database. These URLs are not meant to be used outside of Sahara.

Sahara Swift URLs passed to running jobs as input or output sources include a ".sahara" suffix on the container, for example:

```
swift://container.sahara/object
```

You may notice these Swift URLs in job logs, however, you do not need to add the suffix to the containers yourself. Sahara will add the suffix if necessary, so when using the UI or the python client you may write the above URL simply as:

```
swift://container/object
```

Sahara internal database URLs have the form:

```
internal-db://sahara-generated-uuid
```

This indicates a file object in the Sahara database which has the given uuid as a key

# 2.17 EDP Requirements

The OpenStack installation and the cluster launched from Sahara must meet the following minimum requirements in order for EDP to function:

## 2.17.1 OpenStack Services

When a Hadoop job is executed, binaries are first uploaded to a cluster node and then moved from the node local filesystem to HDFS. Therefore, there must be an instance of HDFS available to the nodes in the Sahara cluster.

If the Swift service is not running in the OpenStack installation

- Job binaries may only be stored in the Sahara internal database
- Data sources require a long-running HDFS

If the Swift service is running in the OpenStack installation

- Job binaries may be stored in Swift or the Sahara internal database
- Data sources may be in Swift or a long-running HDFS

### 2.17.2 Cluster Processes

Requirements for EDP support depend on the EDP job type and plugin used for the cluster. For example a Vanilla Sahara cluster must run at least one instance of these processes to support EDP:

- For Hadoop version 1:
  - jobtracker
  - namenode
  - oozie
  - tasktracker
  - datanode
- For Hadoop version 2:
  - namenode
  - datanode
  - resourcemanager
  - nodemanager
  - historyserver
  - oozie

# 2.18 EDP Technical Considerations

There are several things in EDP which require attention in order to work properly. They are listed on this page.

### 2.18.1 Transient Clusters

EDP allows running jobs on transient clusters. In this case the cluster is created specifically for the job and is shut down automatically once the job is finished.

Two config parameters control the behaviour of periodic clusters:

• periodic\_enable - if set to 'False', Sahara will do nothing to a transient cluster once the job it was created for is completed. If it is set to 'True', then the behaviour depends on the value of the next parameter.

• use\_identity\_api\_v3 - set it to 'False' if your OpenStack installation does not provide Keystone API v3. In that case Sahara will not terminate unneeded clusters. Instead it will set their state to 'AwaitingTermination' meaning that they could be manually deleted by a user. If the parameter is set to 'True', Sahara will itself terminate the cluster. The limitation is caused by lack of 'trusts' feature in Keystone API older than v3.

If both parameters are set to 'True', Sahara works with transient clusters in the following manner:

- 1. When a user requests for a job to be executed on a transient cluster, Sahara creates such a cluster.
- 2. Sahara drops the user's credentials once the cluster is created but prior to that it creates a trust allowing it to operate with the cluster instances in the future without user credentials.
- 3. Once a cluster is not needed, Sahara terminates its instances using the stored trust. Sahara drops the trust after that.

API

## 2.19 Sahara REST API v1.1

### 2.19.1 1 General API information

This section contains base info about the Sahara REST API design.

#### 1.1 Authentication and Authorization

The Sahara API uses the Keystone Identity Service as the default authentication service. When Keystone is enabled, users who submit requests to the Sahara service must provide an authentication token in the X-Auth-Token request header. A user can obtain the token by authenticating to the Keystone endpoint. For more information about Keystone, see the OpenStack Identity Developer Guide.

Also with each request a user must specify the OpenStack tenant in the url path, for example: '/v1.1/{tenant\_id}/clusters'. Sahara will perform the requested operation in the specified tenant using the provided credentials. Therefore, clusters may be created and managed only within tenants to which the user has access.

### 1.2 Request / Response Types

The Sahara API supports the JSON data serialization format. This means that for requests that contain a body, the Content-Type header must be set to the MIME type value "application/json". Also, clients should accept JSON serialized responses by specifying the Accept header with the MIME type value "application/json" or adding the ".json" extension to the resource name. The default response format is "application/json" if the client does not specify an Accept header or append the ".json" extension in the URL path.

#### Example:

```
GET /v1.1/{tenant_id}/clusters.json
or
GET /v1.1/{tenant_id}/clusters
Accept: application/json
```

#### 1.3 Faults

The Sahara API returns an error response if a failure occurs while processing a request. Sahara uses only standard HTTP error codes. 4xx errors indicate problems in the particular request being sent from the client and 5xx errors indicate server-side problems.

The response body will contain richer information about the cause of the error. An error response follows the format illustrated by the following example:

```
HTTP/1.1 400 BAD REQUEST
Content-type: application/json
Content-length: 126

{
    "error_name": "CLUSTER_NAME_ALREADY_EXISTS",
    "error_message": "Cluster with name 'test-cluster' already exists",
    "error_code": 400
}
```

The 'error\_code' attribute is an HTTP response code. The 'error\_name' attribute indicates the generic error type without any concrete ids or names, etc. The last attribute, 'error\_message', contains a human readable error description.

### 2.19.2 2 API

• Sahara REST API Reference (OpenStack API Complete Reference - DataProcessing)

#### Miscellaneous

# 2.20 Requirements for Guests

Sahara manages guests of various platforms (for example Ubuntu, Fedora, RHEL, and CentOS) with various versions of the Hadoop ecosystem projects installed. There are common requirements for all guests, and additional requirements based on the plugin that is used for cluster deployment.

## 2.20.1 Common Requirements

- The operating system must be Linux
- cloud-init must be installed
- ssh-server must be installed
  - if a firewall is active it must allow connections on port 22 to enable ssh

# 2.20.2 Vanilla Plugin Requirements

If the Vanilla Plugin is used for cluster deployment the guest is required to have

- ssh-client installed
- Java (version >= 6)
- · Apache Hadoop installed
- 'hadoop' user created

See *Swift Integration* for information on using Swift with your Sahara cluster (for EDP support Swift integration is currently required).

To support EDP, the following components must also be installed on the guest:

- Oozie version 4 or higher
- mysql
- hive

See Building Images for Vanilla Plugin for instructions on building images for this plugin.

## 2.20.3 HDP Plugin

This plugin does not have any additional requirements. Currently, only the CentOS Linux distribution is supported but other distributions will be supported in the future. To speed up provisioning, the HDP packages can be pre-installed on the image used. The packages' versions depend on the HDP version being used.

## 2.20.4 Cloudera Plugin Requirements

If the Cloudera Plugin is used for cluster deployment the guest is required to have

Cloudera Express installed

See Building Images for Cloudera Plugin for instructions on building images for this plugin.

# 2.21 Swift Integration

Hadoop and Swift integration are the essential continuation of the Hadoop/OpenStack marriage. The key component to making this marriage work is the Hadoop Swift filesystem implementation. Although this implementation has been merged into the upstream Hadoop project, Sahara maintains a version with the most current features enabled.

- The original Hadoop patch can be found at https://issues.apache.org/jira/browse/HADOOP-8545
- The most current Sahara maintained version of this patch can be found in the Sahara Extra repository https://github.com/openstack/sahara-extra
- The latest compiled version of the jar for this component can be downloaded from http://sahara-files.mirantis.com/hadoop-swift/hadoop-swift-latest.jar

# 2.21.1 Hadoop patching

You may build the jar file yourself by choosing the latest patch from the Sahara Extra repository and using Maven to build with the pom.xml file provided. Or you may get the latest jar pre-built from the CDN at http://sahara-files.mirantis.com/hadoop-swift/hadoop-swift-latest.jar

You will need to put this file into the hadoop libraries (e.g. /usr/lib/share/hadoop/lib) on each job-tracker and task-tracker node for Hadoop 1.x, or each ResourceManager and NodeManager node for Hadoop 2.x in the cluster.

## 2.21.2 Hadoop configurations

In general, when Sahara runs a job on a cluster it will handle configuring the Hadoop installation. In cases where a user might require more in-depth configuration all the data is set in the core-site.xml file on the cluster instances using this template:

There are two types of configs here:

- 1. General. The \${name} in this case equals to fs.swift. Here is the list of \${config}:
  - .impl Swift FileSystem implementation. The \${value} is org.apache.hadoop.fs.swift.snative.SwiftNativeFileSystem
  - .connect.timeout timeout for all connections by default: 15000
  - .socket.timeout how long the connection waits for responses from servers. by default: 60000
  - .connect.retry.count connection retry count for all connections. by default: 3
  - .connect.throttle.delay delay in millis between bulk (delete, rename, copy operations). by default: 0
  - .blocksize blocksize for filesystem. By default: 32Mb
  - .partsize the partition size for uploads. By default: 4608\*1024Kb
  - .requestsize request size for reads in KB. By default: 64Kb
- 2. Provider-specific. The patch for Hadoop supports different cloud providers. The \${name} in this case equals to fs.swift.service.\${provider}.

Here is the list of \${config}:

- .auth.url authorization URL
- .tenant
- .username
- · .password
- .domain.name Domains can be used to specify users who are not in the tenant specified.
- .trust.id-Trusts are optionally used to scope the authentication tokens of the supplied user.
- .http.port
- .https.port
- region Swift region is used when cloud has more than one Swift installation. If region param is not set first region from Keystone endpoint list will be chosen. If region param not found exception will be thrown.
- .location-aware turn On location awareness. Is false by default
- · .apikey
- .public

# **2.21.3 Example**

For this example it is assumed that you have setup a Hadoop instance with a valid configuration and the Swift filesystem component. Furthermore there is assumed to be a Swift container named integration holding an object named temp, as well as a Keystone user named admin with a password of swordfish.

The following example illustrates how to copy an object to a new location in the same container. We will use Hadoop's distop command (http://hadoop.apache.org/docs/r0.19.0/distop.html) to accomplish the copy. Note that the service provider for our Swift access is sahara, and that we will not need to specify the project of our Swift container as it will be provided in the Hadoop configuration.

Swift paths are expressed in Hadoop according to the following template: swift://\${container}.\${provider}/\${object}. For our example source this will appear as swift://integration.sahara/temp.

#### Let's run the job:

```
$ hadoop distcp -D fs.swift.service.sahara.username=admin \
  -D fs.swift.service.sahara.password=swordfish \
  swift://integration.sahara/temp swift://integration.sahara/temp1
```

After that just confirm that temp1 has been created in our integration container.

### 2.21.4 Limitations

Note: Please note that container names should be a valid URI.

# 2.22 Building Images for Vanilla Plugin

In this document you will find instruction on how to build Ubuntu, Fedora, and CentOS images with Apache Hadoop versions 1.x.x and 2.x.x.

As of now the vanilla plugin works with images with pre-installed versions of Apache Hadoop. To simplify the task of building such images we use Disk Image Builder.

*Disk Image Builder* builds disk images using elements. An element is a particular set of code that alters how the image is built, or runs within the chroot to prepare the image.

Elements for building vanilla images are stored in Sahara extra repository

Note: Sahara requires images with cloud-init package installed:

- For Fedora
- For Ubuntu

To create vanilla images follow these steps:

- 1. Clone repository "https://github.com/openstack/sahara-image-elements" locally.
- 2. Run the diskimage-create.sh script.

You can run the script diskimage-create.sh in any directory (for example, in your home directory). By default this script will attempt to create cloud images for all versions of supported plugins and all operating systems (subset of Ubuntu, Fedora, and CentOS depending on plugin). This script must be run with root privileges.

```
sudo bash diskimage-create.sh
```

This scripts will update your system and install required packages:

- kpartx
- qemu

Then it will clone the repositories "https://github.com/openstack/diskimage-builder" and "https://github.com/openstack/sa

- DIB\_HADOOP\_VERSION version of Hadoop to install
- JAVA\_DOWNLOAD\_URL download link for JDK (tarball or bin)
- OOZIE\_DOWNLOAD\_URL download link for OOZIE (we have built Oozie libs here: http://sahara-files.mirantis.com/oozie-4.0.0.tar.gz)
- HIVE\_VERSION version of Hive to install (currently supports only 0.11.0)
- ubuntu\_image\_name
- fedora\_image\_name
- DIB\_IMAGE\_SIZE parameter that specifies a volume of hard disk of instance. You need to specify it only for Fedora because Fedora doesn't use all available volume
- DIB\_COMMIT\_ID latest commit id of diskimage-builder project
- SAHARA\_ELEMENTS\_COMMIT\_ID latest commit id of sahara-image-elements project

NOTE: If you don't want to use default values, you should set your values of parameters.

Then it will create required cloud images using image elements that install all the necessary packages and configure them. You will find created images in the current directory.

**Note:** Disk Image Builder will generate QCOW2 images, used with the default OpenStack Qemu/KVM hypervisors. If your OpenStack uses a different hypervisor, the generated image should be converted to an appropriate format.

VMware Nova backend requires VMDK image format. You may use qemu-img utility to convert a QCOW2 image to VMDK.

```
qemu-img convert -0 vmdk <original_image>.qcow2 <converted_image>.vmdk
```

For finer control of diskimage-create.sh see the official documentation or run:

```
$ diskimage-create.sh -h
```

# 2.23 Building Images for Cloudera Plugin

In this document you will find instructions on how to build Ubuntu and CentOS images with Cloudera Express (now only 5.0.0 and 5.3.0 versions are supported).

Apache Hadoop. To simplify the task of building such images we use Disk Image Builder.

*Disk Image Builder* builds disk images using elements. An element is a particular set of code that alters how the image is built, or runs within the chroot to prepare the image.

Elements for building Cloudera images are stored in Sahara extra repository

**Note:** Sahara requires images with cloud-init package installed:

• For CentOS

#### • For Ubuntu

To create cloudera images follow these steps:

- 1. Clone repository "https://github.com/openstack/sahara-image-elements" locally.
- 2. Run the diskimage-create.sh script.

You can run the script diskimage-create.sh in any directory (for example, in your home directory). By default this script will attempt to create cloud images for all versions of supported plugins and all operating systems (subset of Ubuntu, Fedora, and CentOS depending on plugin). To only create Cloudera images, you should use the "-p cloudera" parameter in the command line. If you want to create the image only for a specific operating system, you should use the "-i ubuntulcentos" parameter to assign the operating system (the cloudera plugin only supports Ubuntu and Centos). If you want to create the image only for a specific Cloudera version, you should use the "-v 5.0|5.3" parameter to assign the version. Below is an example to create Cloudera images for both Ubuntu and CentOS with Cloudera Express 5.3.0 version.

```
bash diskimage-create.sh -p cloudera -v 5.3
```

If you want to create only an Ubuntu image, you may use following example for that.

```
bash diskimage-create.sh -p cloudera -i ubuntu -v 5.3
```

NOTE: If you don't want to use default values, you should explicitly set the values of your required parameters.

The script will create required cloud images using image elements that install all the necessary packages and configure them. You will find the created images in the current directory.

**Note:** Disk Image Builder will generate QCOW2 images, used with the default OpenStack Qemu/KVM hypervisors. If your OpenStack uses a different hypervisor, the generated image should be converted to an appropriate format.

The VMware Nova backend requires the VMDK image format. You may use qemu-img utility to convert a QCOW2 image to VMDK.

```
qemu-img convert -0 vmdk <original_image>.qcow2 <converted_image>.vmdk
```

For finer control of diskimage-create.sh see the official documentation or run:

```
$ diskimage-create.sh -h
```

# **Developer Guide**

### **Programming HowTos and Tutorials**

# 3.1 Development Guidelines

## 3.1.1 Coding Guidelines

For all the code in Sahara we have a rule - it should pass PEP 8.

To check your code against PEP 8 run:

```
$ tox -e pep8
```

**Note:** For more details on coding guidelines see file HACKING.rst in the root of Sahara repo.

## 3.1.2 Modification of Upstream Files

We never modify upstream files in Sahara. Any changes in upstream files should be made in the upstream project and then merged back in to Sahara. This includes whitespace changes, comments, and typos. Any change requests containing upstream file modifications are almost certain to receive lots of negative reviews. Be warned.

Examples of upstream files are default xml configuration files used to configure Hadoop, or code imported from the OpenStack Oslo project. The xml files will usually be found in resource directories with an accompanying README file that identifies where the files came from. For example:

```
$ pwd
/home/me/sahara/sahara/plugins/vanilla/v2_3_0/resources
$ ls
core-default.xml hdfs-default.xml oozie-default.xml README.rst
create_oozie_db.sql mapred-default.xml post_conf.template yarn-default.xml
```

## 3.1.3 Testing Guidelines

Sahara has a suite of tests that are run on all submitted code, and it is recommended that developers execute the tests themselves to catch regressions early. Developers are also expected to keep the test suite up-to-date with any submitted code changes.

Unit tests are located at sahara/tests.

Sahara's suite of unit tests can be executed in an isolated environment with Tox. To execute the unit tests run the following from the root of Sahara repo:

```
$ tox -e py27
```

### 3.1.4 Documentation Guidelines

All Sahara docs are written using Sphinx / RST and located in the main repo in doc directory. You can add/edit pages here to update http://docs.openstack.org/developer/sahara site.

The documentation in docstrings should follow the PEP 257 conventions (as mentioned in the PEP 8 guidelines).

More specifically:

- 1. Triple quotes should be used for all docstrings.
- 2. If the docstring is simple and fits on one line, then just use one line.
- 3. For docstrings that take multiple lines, there should be a newline after the opening quotes, and before the closing quotes.
- 4. Sphinx is used to build documentation, so use the restructured text markup to designate parameters, return values, etc. Documentation on the sphinx specific markup can be found here:

Run the following command to build docs locally.

```
$ tox -e docs
```

After it you can access generated docs in doc/build/ directory, for example, main page -doc/build/html/index.html.

To make docs generation process faster you can use:

```
$ SPHINX_DEBUG=1 tox -e docs
```

or to avoid sahara reinstallation to virtual env each time you want to rebuild docs you can use the following command (it could be executed only after running tox -e docs first time):

```
$ SPHINX_DEBUG=1 .tox/docs/bin/python setup.py build_sphinx
```

**Note:** For more details on documentation guidelines see file HACKING.rst in the root of Sahara repo.

## 3.1.5 Event log Guidelines

Currently Sahara keep with cluster useful information about provisioning. Cluster provisioning can be represented as a linear series of provisioning steps, which are executed one after another. Also each step would consist of several events. The amount of events depends on the step and the amount of instances in the cluster. Also each event can contain information about cluster, instance, and node group. In case of errors, this event would contain information about reasons of errors. Each exception in sahara contains a unique identifier that will allow the user to find extra information about the reasons for errors in the sahara logs. Here http://developer.openstack.org/api-ref-data-processing-v1.1.html#v1.1eventlog you can see an example of provisioning progress information.

This means that if you add some important phase for cluster provisioning to sahara code, it's recommended to add new provisioning step for this phase. It would allow users to use event log for handling errors during this phase.

Sahara already have special utils for operating provisioning steps and events in module sahara/utils/cluster\_progress\_ops.py.

**Note:** It's strictly recommended not use conductor event log ops directly to assign events and operate provisioning steps.

**Note:** You should not add a new provisioning step until the previous step successfully completed.

**Note:** It's strictly recommended to use event\_wrapper for events handling

# 3.2 Setting Up a Development Environment

This page describes how to setup a Sahara development environment by either installing it as a part of DevStack or pointing a local running instance at an external OpenStack. You should be able to debug and test your changes without having to deploy Sahara.

## 3.2.1 Setup a Local Environment with Sahara inside DevStack

See the main article.

## 3.2.2 Setup a Local Environment with an external OpenStack

1. Install prerequisites

#### On OS X Systems:

- # we actually need pip, which is part of python package
  \$ brew install python mysql postgresql
  \$ pip install virtualenv tox
- On Ubuntu:

```
$ sudo apt-get update
```

\$ sudo apt-get install git-core python-dev python-virtualenv gcc libpq-dev libmysqlclient-dev python-\$ sudo pip install tox

### On Fedora-based distributions (e.g., Fedora/RHEL/CentOS/Scientific Linux):

\$ sudo yum install git-core python-devel python-virtualenv gcc python-pip mariadb-devel postgresql-de \$ sudo pip install tox

## On openSUSE-based distributions (SLES 12, openSUSE, Factory or Tumbleweed):

.. sourcecode:: console

\$ sudo zypper in gcc git libmysqlclient-devel postgresql-devel python-devel python-pip python-tox python-virtualenv

2. Grab the code:

```
$ git clone git://github.com/openstack/sahara.git
$ cd sahara
```

3.1 Generate Sahara sample using tox:

```
tox -e genconfig
```

3.2 Create config file from the sample:

- \$ cp ./etc/sahara/sahara.conf.sample ./etc/sahara/sahara.conf
  - 4. Look through the sahara.conf and modify parameter values as needed. For details see *Sahara Configuration Guide*
  - 5. Create database schema:
- \$ tox -e venv -- sahara-db-manage --config-file etc/sahara/sahara.conf upgrade head
  - 6. To start Sahara call:
- \$ tox -e venv -- sahara-all --config-file etc/sahara/sahara.conf --debug

# 3.2.3 Setup local OpenStack dashboard with Sahara plugin

## Sahara UI Dev Environment Setup

This page describes how to setup Horizon for developing Sahara by either installing it as part of DevStack with Sahara or installing it in an isolated environment and running from the command line.

#### Install as a part of DevStack

See the DevStack guide for more information on installing and configuring DevStack with Sahara.

After Horizon installation, it will contain a Data Processing tab under Projects tab. Sahara UI source code will be located at \$DEST/horizon/openstack\_dashboard/dashboards/project/data\_processing where \$DEST/ is usually /opt/stack/.

#### **Isolated Dashboard for Sahara**

### These installation steps serve two purposes:

- 1. Setup a dev environment
- 2. Setup an isolated Dashboard for Sahara

**Note** The host where you are going to perform installation has to be able to connect to all OpenStack endpoints. You can list all available endpoints using the following command:

\$ keystone endpoint-list

You can list the registered services with this command:

- \$ keystone service-list
  - 1. Install prerequisites

```
$ sudo apt-get update
```

\$ sudo apt-get install git-core python-dev gcc python-setuptools python-virtualenv node-less lik

On Ubuntu 12.10 and higher you have to install the following lib as well:

- \$ sudo apt-get install nodejs-legacy
- 2. Checkout Horizon from git and switch to your version of OpenStack

Here is an example:

\$ git clone https://github.com/openstack/horizon

Then install the virtual environment:

- \$ python tools/install\_venv.py
- 3. Create a local\_settings.py file
  - \$ cp openstack\_dashboard/local/local\_settings.py.example openstack\_dashboard/local/local\_setting
- 4. Modify openstack\_dashboard/local/local\_settings.py

Set the proper values for host and url variables:

```
OPENSTACK_HOST = "ip of your controller"
```

If you are using Nova-Network with auto\_assign\_floating\_ip=True add the following parameter:

```
SAHARA_AUTO_IP_ALLOCATION_ENABLED = True
```

- 5. If Sahara is not registered with the keystone service catalog, it may be added with the following commands. To use Sahara from Horizon without keystone registration, see Using the Data Processing Dashboard without Keystone Registration.
  - \$ keystone service-create --name sahara --type data-processing
  - \$ keystone endpoint-create --region RegionOne --service sahara --publicurl 'http://localhost:838

**Note** you should replace the ip and port in with the appropriate values.

- 6. Start Horizon
  - \$ tools/with\_venv.sh python manage.py runserver 0.0.0.0:8080

This will start Horizon in debug mode. That means the logs will be written to console and if any exceptions happen, you will see the stack-trace rendered as a web-page.

Debug mode can be disabled by changing DEBUG=True to False in local\_settings.py. In that case Horizon should be started slightly differently, otherwise it will not serve static files:

\$ tools/with\_venv.sh python manage.py runserver --insecure 0.0.0.0:8080

Note It is not recommended to use Horizon in this mode for production.

7. Applying changes

If you have changed any \*.py files in horizon/openstack\_dashboard/dashboards/project/data\_processin directory, Horizon will notice that and reload automatically. However changes made to non-python files may not be noticed, so you have to restart Horizon again manually, as described in step 6.

Using the Data Processing Dashboard without Keystone Registration Note These modifications are strictly for a development environment

If Sahara is not registered as a service with keystone, Horizon must be modified so that the Sahara URL can be known and so service-based permissions do not prevent the Data Processing dashboard from displaying.

1. Modify openstack\_dashboard/api/sahara.py:

Add the following lines before def client (request):

Note you should replace the ip and port in SAHARA\_URL with the appropriate values.

```
SAHARA_URL = "http://localhost:8386/v1.1"

def get_sahara_url(request):
    if SAHARA_URL:
        url = SAHARA_URL.rstrip('/')
        if url.split('/')[-1] in ['v1.0', 'v1.1']:
            url = SAHARA_URL + '/' + request.user.tenant_id
        return url

    return base.url_for(request, SAHARA_SERVICE)
```

After that modify sahara\_url provided in def client (request):

```
sahara_url=get_sahara_url(request)
```

2. Modify openstack dashboard/dashboards/project/dashboard.py:

Overload the register method in class Project to programmatically remove data-processing permissions from all panels.

Alternatively the data-processing permissions can be removed manually from each panel under openstack\_dashboard/dashboards/project/data\_processing

## 3.2.4 Tips and tricks for dev environment

1. Pip speedup

Add the following lines to ~/.pip/pip.conf

#### [global]

62

```
download-cache = /home/<username>/.pip/cache
index-url = <mirror url>
```

Note that the  $\sim$ /.pip/cache folder should be created manually.

2. Git hook for fast checks

Just add the following lines to .git/hooks/pre-commit and do chmod +x for it.

```
#!/bin/sh
# Run fast checks (PEP8 style check and PyFlakes fast static analysis)
tools/run_fast_checks
```

You can added the same check for pre-push, for example, run\_tests and run\_pylint.

3. Running static analysis (PyLint)

Just run the following command

```
tox -e pylint
```

# 3.3 Setup DevStack

The DevStack could be installed on Fedora, Ubuntu and CentOS. For supported versions see DevStack documentation

We recommend to install DevStack not into your main system, but run it in a VM instead. That way you may avoid contamination of your system with various stuff. You may find hypervisor and VM requirements in the the next section. If you still want to install DevStack on top of your main system, just skip the next section and read further.

# 3.3.1 Start VM and set up OS

In order to run DevStack in a local VM, you need to start by installing a guest with Ubuntu 12.04 server. Download an image file from Ubuntu's web site and create a new guest from it. Virtualization solution must support nested virtualization. Without nested virtualization VMs running inside the DevStack will be extremely slow lacking hardware acceleration, i.e. you will run QEMU VMs without KVM.

On Linux QEMU/KVM supports nested virtualization, on Mac OS - VMware Fusion. VMware Fusion requires adjustments to run VM with fixed IP. You may find instructions which can help *below*.

Start a new VM with Ubuntu Server 12.04. Recommended settings:

- Processor at least 2 cores
- Memory at least 8GB
- Hard Drive at least 60GB

When allocating CPUs and RAM to the DevStack, assess how big clusters you want to run. A single Hadoop VM needs at least 1 cpu and 1G of RAM to run. While it is possible for several VMs to share a single cpu core, remember that they can't share the RAM.

After you installed the VM, connect to it via SSH and proceed with the instructions below.

### 3.3.2 Install DevStack

The instructions assume that you've decided to install DevStack into Ubuntu 12.04 system.

1. Clone DevStack:

```
$ sudo apt-get install git-core
$ git clone https://git.openstack.org/cgit/openstack-dev/devstack.git
```

2. Create file local.conf in devstack directory with the following content:

```
[[local|localrc]]
ADMIN_PASSWORD=nova
MYSQL_PASSWORD=nova
RABBIT_PASSWORD=nova
SERVICE_PASSWORD=$ADMIN_PASSWORD
SERVICE_TOKEN=nova
# Enable Swift
enable_service s-proxy s-object s-container s-account
```

```
SWIFT_HASH=66a3d6b56c1f479c8b4e70ab5c2000f5
SWIFT_REPLICAS=1
SWIFT_DATA_DIR=$DEST/data
# Force checkout prerequisites
# FORCE_PREREQ=1
# keystone is now configured by default to use PKI as the token format which produces huge tokens.
# set UUID as keystone token format which is much shorter and easier to work with.
KEYSTONE_TOKEN_FORMAT=UUID
# Change the FLOATING_RANGE to whatever IPs VM is working in.
# In NAT mode it is subnet VMware Fusion provides, in bridged mode it is your local network.
# But only use the top end of the network by using a /27 and starting at the 224 octet.
FLOATING_RANGE=192.168.55.224/27
# Enable logging
SCREEN_LOGDIR=$DEST/logs/screen
# Set ``OFFLINE`` to ``True`` to configure ``stack.sh`` to run cleanly without
# Internet access. ``stack.sh`` must have been previously run with Internet
# access to install prerequisites and fetch repositories.
# OFFLINE=True
# Enable Sahara
enable_service sahara
```

3. Sahara can send notifications to Ceilometer, if Ceilometer is enabled. If you want to enable Ceilometer add the following lines to local.conf file:

```
enable_service ceilometer-acompute ceilometer-acentral ceilometer-anotification ceilometer-collector enable_service ceilometer-alarm-evaluator,ceilometer-alarm-notifier enable_service ceilometer-api
```

- 4. Start DevStack:
- \$ ./stack.sh
  - 5. Once previous step is finished Devstack will print Horizon URL. Navigate to this URL and login with login "admin" and password from local.conf.
  - 6. Congratulations! You have OpenStack running in your VM and ready to launch VMs inside that VM:)

## 3.3.3 Managing Sahara in DevStack

If you install DevStack with Sahara included you can rejoin screen with rejoin-stack.sh command and switch to sahara tab. Here you can manage the Sahara service as other OpenStack services. Sahara source code is located at \$DEST/sahara which is usually /opt/stack/sahara.

## 3.3.4 Setting fixed IP address for VMware Fusion VM

- 1. Open file /Library/Preferences/VMware Fusion/vmnet8/dhcpd.conf
- 2. There is a block named "subnet". It might look like this:

```
subnet 192.168.55.0 netmask 255.255.255.0 {
    range 192.168.55.128 192.168.55.254;
```

- 3. You need to pick an IP address outside of that range. For example 192.168.55.20
- 4. Copy VM MAC address from VM settings->Network->Advanced
- 5. Append the following block to file dhcpd.conf (don't forget to replace VM\_HOSTNAME and VM\_MAC\_ADDRESS with actual values):

```
host VM_HOSTNAME {
     hardware ethernet VM_MAC_ADDRESS;
     fixed-address 192.168.55.20;
}
```

6. Now quit all the VmWare Fusion applications and restart vmnet:

```
$ sudo /Applications/VMware\ Fusion.app/Contents/Library/vmnet-cli --stop
$ sudo /Applications/VMware\ Fusion.app/Contents/Library/vmnet-cli --start
```

7. Now start your VM, it should have new fixed IP address

# 3.4 Sahara UI Dev Environment Setup

This page describes how to setup Horizon for developing Sahara by either installing it as part of DevStack with Sahara or installing it in an isolated environment and running from the command line.

## 3.4.1 Install as a part of DevStack

See the DevStack guide for more information on installing and configuring DevStack with Sahara.

After Horizon installation, it will contain a Data Processing tab under Projects tab. Sahara UI source code will be located at \$DEST/horizon/openstack\_dashboard/dashboards/project/data\_processing where \$DEST/ is usually /opt/stack/.

#### 3.4.2 Isolated Dashboard for Sahara

These installation steps serve two purposes:

- 1. Setup a dev environment
- 2. Setup an isolated Dashboard for Sahara

**Note** The host where you are going to perform installation has to be able to connect to all OpenStack endpoints. You can list all available endpoints using the following command:

\$ keystone endpoint-list

You can list the registered services with this command:

- \$ keystone service-list
  - 1. Install prerequisites

```
$ sudo apt-get update
```

\$ sudo apt-get install git-core python-dev gcc python-setuptools python-virtualenv node-less lik

On Ubuntu 12.10 and higher you have to install the following lib as well:

- \$ sudo apt-get install nodejs-legacy
- 2. Checkout Horizon from git and switch to your version of OpenStack

Here is an example:

\$ git clone https://github.com/openstack/horizon

Then install the virtual environment:

- \$ python tools/install\_venv.py
- 3. Create a local\_settings.py file
  - \$ cp openstack\_dashboard/local/local\_settings.py.example openstack\_dashboard/local/local\_setting
- 4. Modify openstack\_dashboard/local/local\_settings.py

Set the proper values for host and url variables:

```
OPENSTACK_HOST = "ip of your controller"
```

If you are using Nova-Network with auto\_assign\_floating\_ip=True add the following parameter:

```
SAHARA_AUTO_IP_ALLOCATION_ENABLED = True
```

- 5. If Sahara is not registered with the keystone service catalog, it may be added with the following commands. To use Sahara from Horizon without keystone registration, see Using the Data Processing Dashboard without Keystone Registration.
  - \$ keystone service-create --name sahara --type data-processing
  - \$ keystone endpoint-create --region RegionOne --service sahara --publicurl 'http://localhost:838

**Note** you should replace the ip and port in with the appropriate values.

- 6. Start Horizon
  - \$ tools/with\_venv.sh python manage.py runserver 0.0.0.0:8080

This will start Horizon in debug mode. That means the logs will be written to console and if any exceptions happen, you will see the stack-trace rendered as a web-page.

Debug mode can be disabled by changing DEBUG=True to False in local\_settings.py. In that case Horizon should be started slightly differently, otherwise it will not serve static files:

\$ tools/with\_venv.sh python manage.py runserver --insecure 0.0.0.0:8080

Note It is not recommended to use Horizon in this mode for production.

7. Applying changes

If you have changed any \*.py files in horizon/openstack\_dashboard/dashboards/project/data\_processin directory, Horizon will notice that and reload automatically. However changes made to non-python files may not be noticed, so you have to restart Horizon again manually, as described in step 6.

#### Using the Data Processing Dashboard without Keystone Registration

**Note** These modifications are strictly for a development environment

If Sahara is not registered as a service with keystone, Horizon must be modified so that the Sahara URL can be known and so service-based permissions do not prevent the Data Processing dashboard from displaying.

1. Modify openstack\_dashboard/api/sahara.py:

Add the following lines before def client (request):

Note you should replace the ip and port in SAHARA\_URL with the appropriate values.

```
SAHARA_URL = "http://localhost:8386/v1.1"
def get_sahara_url(request):
    if SAHARA_URL:
        url = SAHARA_URL.rstrip('/')
        if url.split('/')[-1] in ['v1.0', 'v1.1']:
            url = SAHARA_URL + '/' + request.user.tenant_id
        return url
    return base.url_for(request, SAHARA_SERVICE)
```

After that modify sahara\_url provided in def client (request):

```
sahara_url=get_sahara_url(request)
```

2. Modify openstack dashboard/dashboards/project/dashboard.py:

Overload the register method in class Project to programmatically remove data-processing permissions from all panels.

```
@classmethod
def register(cls, panel):
    if hasattr(panel, 'permissions'):
       panel.permissions = tuple(
           [perm for perm in panel.permissions if not perm.startswith(
               'openstack.services.data_processing')])
    super(Project, cls).register(panel)
```

Alternatively the data-processing permissions can be removed manually from each panel under openstack\_dashboard/dashboards/project/data\_processing

# 3.5 Quickstart guide

This guide will help you setup a vanilla Hadoop cluster using a combination of OpenStack command line tools and the sahara REST API.

### 3.5.1 1. Install sahara

• If you want to hack the code follow Setting Up a Development Environment.

OR

• If you just want to install and use Sahara follow Sahara Installation Guide.

## 3.5.2 2. Identity service configuration

To use the OpenStack command line tools you should specify environment variables with the configuration details for your OpenStack installation. The following example assumes that the Identity service is at 127.0.0.1:5000, with a user admin in the admin tenant whose password is nova:

```
$ export OS_AUTH_URL=http://127.0.0.1:5000/v2.0/
$ export OS_TENANT_NAME=admin
$ export OS_USERNAME=admin
$ export OS_PASSWORD=nova
```

With these environment variables set you can get an authentication token using the keystone command line client as follows:

\$ keystone token-get

If authentication succeeds, the output will be as follows:

+		+-		-+
1	Property	I	Value	
т.		т-		
	expires		2013-07-08T15:21:18Z	
	id		dd92e3cdb4e1462690cd444d6b01b746	
	tenant_id		62bd2046841e4e94a87b4a22aa886c13	
	user_id		720fb87141a14fd0b204f977f5f02512	
+		+-		-+

The id and tenant\_id values will be used for creating REST calls to sahara and should be saved. The id value is the token provided by the Identity service, and the tenant\_id is the UUID for the tenant name specified earlier. These values should be exported to environment variables for ease of use later.

```
$ export AUTH_TOKEN="dd92e3cdb4e1462690cd444d6b01b746"
$ export TENANT_ID="62bd2046841e4e94a87b4a22aa886c13"
```

## 3.5.3 3. Upload an image to the Image service

You will need to upload a virtual machine image to the OpenStack Image service. You can download pre-built images with vanilla Apache Hadoop installed, or build the images yourself:

• Download and install a pre-built image with Ubuntu 13.10

```
$ ssh user@hostname
$ wget http://sahara-files.mirantis.com/sahara-icehouse-vanilla-1.2.1-ubuntu-13.10.qcow2
$ glance image-create --name=sahara-icehouse-vanilla-1.2.1-ubuntu-13.10 \
    --disk-format=qcow2 --container-format=bare < ./sahara-icehouse-vanilla-1.2.1-ubuntu-13.10.qcow2</pre>
```

### OR

• with Fedora 20

```
$ ssh user@hostname
$ wget http://sahara-files.mirantis.com/sahara-icehouse-vanilla-1.2.1-fedora-20.qcow2
$ glance image-create --name=sahara-icehouse-vanilla-1.2.1-fedora-20 \
        --disk-format=qcow2 --container-format=bare < ./sahara-icehouse-vanilla-1.2.1-fedora-20.qcow2</pre>
```

### OR

• build the image using Building Images for Vanilla Plugin.

Save the image id, this will be used during the image registration with sahara. You can get the image id using the glance command line tool as follows:

## 3.5.4 4. Register the image with the sahara image registry

Now you will begin to interact with sahara by registering the virtual machine image in the sahara image registry.

Register the image with the username ubuntu. Note, the username will vary depending on the source image used, for more please see Vanilla Plugin

```
$ sahara image-register --id $IMAGE_ID --username ubuntu
```

Tag the image to inform sahara about the plugin with which it shall be used:

```
$ sahara image-add-tag --id $IMAGE_ID --tag vanilla
$ sahara image-add-tag --id $IMAGE_ID --tag 1.2.1
```

Ensure that the image is registered correctly by querying sahara. If registered successfully, the image will appear in the output as follows:

## 3.5.5 5. Create node group templates

Node groups are the building blocks of clusters in sahara. Before you can begin provisioning clusters you must define a few node group templates to describe their configurations.

Note, these templates assume that floating IP addresses are not being used, for more information please see Floating IP management

Create a file named ng\_master\_template\_create.json with the following content:

```
"name": "test-master-tmpl",
    "flavor_id": "2",
    "plugin_name": "vanilla",
    "hadoop_version": "1.2.1",
    "node_processes": ["jobtracker", "namenode"],
    "auto_security_group": true
}

Create a file named ng_worker_template_create.json with the following content:

{
    "name": "test-worker-tmpl",
    "flavor_id": "2",
    "plugin_name": "vanilla",
    "hadoop_version": "1.2.1",
    "node_processes": ["tasktracker", "datanode"],
```

```
"auto_security_group": true
```

Use the sahara client to upload the node group templates:

```
$ sahara node-group-template-create --json ng_master_template_create.json
$ sahara node-group-template-create --json ng_worker_template_create.json
```

List the available node group templates to ensure that they have been added properly:

\$ sahara node-group-template-list

Save the id for the master and worker node group templates as they will be used during cluster template creation. For example:

- Master node group template id: b38227dc-64fe-42bf-8792-d1456b453ef3
- Worker node group template id: 634827b9-6a18-4837-ae15-5371d6ecf02c

# 3.5.6 6. Create a cluster template

The last step before provisioning the cluster is to create a template that describes the node groups of the cluster.

Create a file named cluster\_template\_create.json with the following content:

Upload the Cluster template using the sahara command line tool:

```
$ sahara cluster-template-create --json cluster_template_create.json
```

Save the template id for use in the cluster provisioning command. The cluster id can be found in the output of the creation command or by listing the cluster templates as follows:

#### 3.5.7 7. Create cluster

Now you will provision the cluster. This step requires a few pieces of information that will be found by querying various OpenStack services.

Create a file named cluster create. json with the following content:

```
"name": "cluster-1",
    "plugin_name": "vanilla",
    "hadoop_version": "1.2.1",
    "cluster_template_id": "c0609da7-faac-4dcf-9cbc-858a3aa130cd",
    "user_keypair_id": "stack",
    "default_image_id": "3f9fc974-b484-4756-82a4-bff9e116919b"
    "neutron_management_network": "8cccf998-85e4-4c5f-8850-63d33c1c6916"
}
```

The parameter user\_keypair\_id with the value stack is generated by creating a keypair. You can create your own keypair in the OpenStack Dashboard, or through the nova command line client as follows:

```
$ nova keypair-add stack --pub-key $PATH_TO_PUBLIC_KEY
```

\$ sahara cluster-create -- json cluster\_create.json

If sahara is configured to use neutron for networking, you will also need to include the neutron\_management\_network parameter in cluster\_create.json. Cluster instances will get fixed IP addresses in this network. You can determine the neutron network id with the following command:

\$ neutron net-list

Create and start the cluster:

```
+-----
                      | Value
| Property
       | Validating
| status
| is_transient | False

```

Verify the cluster launched successfully by using the sahara command line tool as follows:

The cluster creation operation may take several minutes to complete. During this time the "status" returned from the previous command may show states other than "Active".

# 3.5.8 8. Run a MapReduce job

Check that your Hadoop installation is working properly by running an example job on the cluster manually.

- Login to the NameNode via ssh:
- \$ ssh ubuntu@<namenode\_ip>
  - Switch to the hadoop user:
- \$ sudo su hadoop
  - Go to the shared hadoop directory and run the simplest MapReduce example:

```
$ cd /usr/share/hadoop
$ hadoop jar hadoop-examples-1.2.1.jar pi 10 100
```

Congratulations! Now you have the Hadoop cluster ready on the OpenStack cloud.

# 3.6 How to Participate

# 3.6.1 Getting started

- Create account on Github (if you don't have one)
  - Make sure that your local git is properly configured by executing git config --list. If not, configure user.name, user.email
- Create account on Launchpad (if you don't have one)
- Subscribe to OpenStack general mail-list
- Subscribe to OpenStack development mail-list
- Create OpenStack profile
- · Login to OpenStack Gerrit with your Launchpad id
  - Sign OpenStack Individual Contributor License Agreement
  - Make sure that your email is listed in identities
- Subscribe to code-reviews. Go to your settings on http://review.openstack.org
  - Go to watched projects
  - Add openstack/sahara, openstack/sahara-extra, openstack/python-saharaclient, openstack/sahara-image-elements

# 3.6.2 How to stay in touch with the community?

- If you have something to discuss use OpenStack development mail-list. Prefix mail subject with [Sahara]
- Join #openstack-sahara IRC channel on freenode
- Weekly on Thursdays at 1400 UTC and 1800 UTC (on alternate weeks)
- IRC channel: #openstack-meeting-alt (1800UTC) and #openstack-meeting-3 (1400UTC)

# 3.6.3 How to send your first patch on review?

- Checkout Sahara code from Github
- · Carefully read http://docs.openstack.org/infra/manual/developers.html#development-workflow
  - Pay special attention to http://docs.openstack.org/infra/manual/developers.html#committing-a-change
- Apply and commit your changes
- Make sure that your code passes PEP8 checks and unit-tests. See Development Guidelines
- Send your patch on review
- Monitor status of your patch review on https://review.openstack.org/#/

## 3.7 How to build Oozie

**Note:** Apache does not make Oozie builds, so it has to be built manually.

#### 3.7.1 Download

- · Download tarball from Apache mirror
- · Unpack it with

```
$ tar -xzvf oozie-4.0.1.tar.gz
```

# 3.7.2 Hadoop Versions

To build Oozie the following command can be used:

```
$ {oozie_dir}/bin/mkdistro.sh -DskipTests
```

#### By default it builds against Hadoop 1.1.1. To built it with 2.x Hadoop version:

• hadoop-2 version in pom.xml files should be changed. It could be done manually or with following command(You should replace 2.x.x to your hadoop version):

```
$ find . -name pom.xml | xargs sed -ri 's/2.3.0/2.x.x/'
```

• build command should be launched with -P hadoop-2 flag

### 3.7.3 JDK Versions

By default, the build configuration enforces that JDK 1.6.\* is being used.

There are 2 build properties that can be used to change the JDK version requirements:

- javaVersion specifies the version of the JDK used to compile (default 1.6)
- targetJavaVersion specifies the version of the generated bytecode (default 1.6)

For example, to specify 1.7 JDK version, build command should contain -D javaVersion=1.7 -D tagetJavaVersion=1.7 flags.

#### 3.7.4 **Build**

To build Ozzie with 2.6.0 hadoop and 1.7 JDK versions following command can be used:

```
$ {oozie_dir}/bin/mkdistro.sh assembly:single -P hadoop-2 -D javaVersion=1.7 -D targetJavaVersion=1.
```

Also, pig version can be passed as maven property with -D pig.version=x.x.x flag.

Similar instruction to build oozie.tar.gz you may find there: http://oozie.apache.org/docs/4.0.0/DG\_QuickStart.html#Building\_Oozie

# 3.8 Adding Database Migrations

The migrations in sahara/db/migration/alembic\_migrations/versions contain the changes needed to migrate between Sahara database revisions. A migration occurs by executing a script that details the changes needed to upgrade or downgrade the database. The migration scripts are ordered so that multiple scripts can run sequentially. The scripts are executed by Sahara's migration wrapper which uses the Alembic library to manage the migration. Sahara supports migration from Icehouse or later.

Any code modifications that change the structure of the database require a migration script so that previously existing databases will continue to function when the new code is released. This page gives a brief overview of how to add the migration.

# 3.8.1 Generate a New Migration Script

New migration scripts can be generated using the sahara-db-manage command.

To generate a migration stub to be filled in by the developer:

```
$ sahara-db-manage --config-file /path/to/sahara.conf revision -m "description of revision"
```

To autogenerate a migration script that reflects the current structure of the database:

```
$ sahara-db-manage --config-file /path/to/sahara.conf revision -m "description of revision" --autoget
```

Each of these commands will create a file of the form revision\_description where revision is a string generated by Alembic and description is based on the text passed with the -m option.

# 3.8.2 Follow the Sahara Naming Convention

By convention Sahara uses 3-digit revision numbers, and this scheme differs from the strings generated by Alembic. Consequently, it's necessary to rename the generated script and modify the revision identifiers in the script.

Open the new script and look for the variable down\_revision. The value should be a 3-digit numeric string, and it identifies the current revision number of the database. Set the revision value to the down\_revision value + 1. For example, the lines:

```
# revision identifiers, used by Alembic.
revision = '507eb70202af'
down_revision = '006'
will become:
# revision identifiers, used by Alembic.
revision = '007'
down_revision = '006'
```

Modify any comments in the file to match the changes and rename the file to match the new revision number:

```
$ mv 507eb70202af_my_new_revision.py 007_my_new_revision.py
```

# 3.8.3 Add Alembic Operations to the Script

The migration script contains method upgrade(). Since Kilo release Sahara doesn't support downgrades. Fill in this method with the appropriate Alembic operations to perform upgrades. In the above example, an upgrade will move from revision '006' to revision '007'.

# 3.8.4 Command Summary for sahara-db-manage

You can upgrade to the latest database version via:

```
$ sahara-db-manage --config-file /path/to/sahara.conf upgrade head
```

To check the current database version:

```
$ sahara-db-manage --config-file /path/to/sahara.conf current
```

To create a script to run the migration offline:

```
$ sahara-db-manage --config-file /path/to/sahara.conf upgrade head --sql
```

To run the offline migration between specific migration versions:

```
$ sahara-db-manage --config-file /path/to/sahara.conf upgrade <start version>:<end version> --sql
```

Upgrade the database incrementally:

```
$ sahara-db-manage --config-file /path/to/sahara.conf upgrade --delta <# of revs>
```

Create new revision:

```
$ sahara-db-manage --config-file /path/to/sahara.conf revision -m "description of revision" --autoget
```

Create a blank file:

```
$ sahara-db-manage --config-file /path/to/sahara.conf revision -m "description of revision"
```

This command does not perform any migrations, it only sets the revision. Revision may be any existing revision. Use this command carefully:

```
$ sahara-db-manage --config-file /path/to/sahara.conf stamp <revision>
```

To verify that the timeline does branch, you can run this command:

```
$ sahara-db-manage --config-file /path/to/sahara.conf check_migration
```

If the migration path does branch, you can find the branch point via:

```
$ sahara-db-manage --config-file /path/to/sahara.conf history
```

# 3.9 Sahara Testing

We have a bunch of different tests for Sahara.

### 3.9.1 Unit Tests

In most Sahara sub repositories we have \_package\_/tests/unit or \_package\_/tests that contains Python unit tests.

### 3.9.2 Integration tests

We have integration tests for the main Sahara service and they are located in *sahara/tests/integration*. The main purpose of these integration tests is to run some kind of scenarios to test Sahara using all plugins. You can find more info about it in *sahara/tests/integration/README.rst*.

# 3.9.3 Scenario integration tests

New scenario integration tests were implemented in Sahara, you can see how use and run it here: sahara/tests/scenario/README.rst

## 3.9.4 Tempest tests

We have some tests in Tempest (https://github.com/openstack/tempest) that are testing Sahara. Here is a list of currently implemented tests:

- REST API tests are checking how the Sahara REST API works. The only part that is not tested is cluster creation, more info about api tests http://docs.openstack.org/developer/tempest/field\_guide/api.html
- CLI tests are checking read-only operations using the Sahara CLI, more info http://docs.openstack.org/developer/tempest/field\_guide/cli.html

# 3.10 Log Guidelines

#### 3.10.1 Levels Guidelines

During Kilo release cycle Sahara community defined the following log levels:

- Debug: Shows everything and is likely not suitable for normal production operation due to the sheer size of logs generated (e.g. scripts executions, process execution, etc.).
- Info: Usually indicates successful service start/stop, versions and such non-error related data. This should include largely positive units of work that are accomplished (e.g. service setup, cluster start, successful job execution).
- Warning: Indicates that there might be a systemic issue; potential predictive failure notice (e.g. job execution failed).
- Error: An error has occurred and an administrator should research the event (e.g. cluster failed to start, plugin violations of operation).
- Critical: An error has occurred and the system might be unstable, anything that eliminates part of Sahara's intended functionality; immediately get administrator assistance (e.g. failed to access keystone/database, plugin load failed).

# 3.10.2 Formatting Guidelines

Now Sahara uses string formatting defined in PEP 3101 for logs.

```
LOG.warning(_LW("Incorrect path: {path}").format(path=path))
```

### 3.10.3 Translation Guidelines

All log levels except Debug requires translation. None of the separate cli tools packaged with Sahara contain log translations.

- · Debug: no translation
- Info: \_LI

Warning: \_LWError: \_LECritical: LC

**Background Concepts for Sahara** 

# 3.11 Pluggable Provisioning Mechanism

Sahara could be integrated with 3rd party management tools like Apache Ambari and Cloudera Management Console. The integration is achieved using plugin mechanism.

In short, responsibilities are divided between Sahara core and plugin as follows. Sahara interacts with user and provisions infrastructure (VMs). Plugin installs and configures Hadoop cluster on the VMs. Optionally Plugin could deploy management and monitoring tools for the cluster. Sahara provides plugin with utility methods to work with VMs.

A plugin must extend *sahara.plugins.provisioning:ProvisioningPluginBase* class and implement all the required methods. Read *Plugin SPI* for details.

The *instance* objects provided by Sahara have *remote* property which could be used to work with VM. The *remote* is a context manager so you can use it in *with instance.remote*: statements. The list of available commands could be found in *sahara.utils.remote.InstanceInteropHelper*. See Vanilla plugin source for usage examples.

# 3.12 Plugin SPI

# 3.12.1 Plugin interface

### get\_versions()

Returns all versions of Hadoop that could be used with the plugin. It is responsibility of the plugin to make sure that all required images for each hadoop version are available, as well as configs and whatever else that plugin needs to create the Hadoop cluster.

Returns: list of strings - Hadoop versions

Example return value: ["1.2.1", "2.3.0", "2.4.1"]

#### get configs(hadoop version)

Lists all configs supported by plugin with descriptions, defaults and targets for which this config is applicable.

Returns: list of configs

Example return value: (("JobTracker heap size", "JobTracker heap size, in MB", "int", "512", "mapreduce", "node", True, 1))

### get\_node\_processes(hadoop\_version)

Returns all supported services and node processes for a given Hadoop version. Each node process belongs to a single service and that relationship is reflected in the returned dict object. See example for details.

Returns: dictionary having entries (service -> list of processes)

Example return value: {"mapreduce": ["tasktracker", "jobtracker"], "hdfs": ["datanode", "namenode"]}

### get\_required\_image\_tags(hadoop\_version)

Lists tags, that should be added to OpenStack Image via Image Registry. Tags are used to filter Images by plugin and hadoop version.

Returns: list of tags

Example return value: ["tag1", "some\_other\_tag", ...]

#### validate(cluster)

Validates a given cluster object. Raises SaharaException with meaningful message.

Returns: None

Example exception: <NotSingleNameNodeException {code='NOT\_SINGLE\_NAME\_NODE', message='Hadoop cluster should contain only 1 NameNode instance. Actual NN count is 2' }>

#### validate scaling(cluster, existing, additional)

To be improved.

Validates a given cluster before scaling operation.

Returns: list of validation\_errors

### update infra(cluster)

Plugin has a chance to change cluster description here. Specifically, plugin must specify image for VMs could change VMs specs in any way it needs. For instance, plugin can ask for additional VMs for the management tool.

Returns: None

#### configure cluster(cluster)

Configures cluster on provisioned by Sahara VMs. In this function plugin should perform all actions like adjusting OS, installing required packages (including Hadoop, if needed), configuring Hadoop, etc.

Returns: None

#### start cluster(cluster)

Start already configured cluster. This method is guaranteed to be called only on cluster which was already prepared with configure\_cluster(...) call.

Returns: None

### scale\_cluster(cluster, instances)

Scale an existing Cluster with additional instances. Instances argument is a list of ready-to-configure instances. Plugin should do all configuration operations in this method and start all services on those instances.

Returns: None

3.12. Plugin SPI 79

#### get edp engine(cluster, job type)

Returns an EDP job engine object that supports the specified job\_type on the given cluster, or None if there is no support. The EDP job engine object returned must implement the interface described in *Elastic Data Processing* (EDP) SPI. The job\_type is a String matching one of the job types listed in *Job Types*.

Returns: an EDP job engine object or None

### decommission\_nodes(cluster, instances)

Scale cluster down by removing a list of instances. Plugin should stop services on a provided list of instances. Plugin also may want to update some configurations on other instances, so this method is the right place to do that.

Returns: None

### convert(config, plugin\_name, version, template\_name, cluster\_template\_create)

Provides plugin with ability to create cluster based on plugin-specific config. Sahara expects plugin to fill in all the required fields. The last argument is the function that plugin should call to save the Cluster Template. See "Cluster Lifecycle for Config File Mode" section below for clarification.

#### on\_terminate\_cluster(cluster)

When user terminates cluster, Sahara simply shuts down all the cluster VMs. This method is guaranteed to be invoked before that, allowing plugin to do some clean-up.

Returns: None

#### get\_open\_ports(node\_group)

When user requests Sahara to automatically create security group for the node group (auto\_security\_group property set to True), Sahara will call this plugin method to get list of ports that need to be opened.

Returns: list of ports to be open in auto security group for the given node group

### def get\_edp\_job\_types(versions)

Optional method, which provides ability to see all supported job types for specified plugin versions

Returns: dict with supported job types for specified versions of plugin

# 3.13 Object Model

Here is a description of all the objects involved in the API.

Notes:

- cluster and node\_group have 'extra' field allowing plugin to persist any complementary info about the cluster.
- node\_process is just a process that runs at some node in cluster.

Example list of node processes:

1. jobtracker

- 2. namenode
- 3. tasktracker
- 4. datanode
- Each plugin may have different names for the same processes.

# 3.13.1 Config

An object, describing one configuration entry

Property	Type	Description
name	string	Config name.
description	string	A hint for user, what this config is used for.
config_type	enum	possible values are: 'string', 'integer', 'boolean', 'enum'.
con-	list	List of possible values, if config_type is enum.
fig_values		
de-	string	Default value for config.
fault_value		
applica-	string	The target could be either a service returned by get_node_processes() call in form of
ble_target		'service: <service name="">', or 'general'.</service>
scope	enum	Could be either 'node' or 'cluster'.
is_optional	bool	If is_optional is False and no default_value is specified, user should provide a value.
priority	int	1 or 2. A Hint for UI. Configs with priority 1 are always displayed. Priority 2 means user
		should click a button to see the config.

# 3.13.2 User Input

Value provided by user for a specific config.

Property	Type	Description
config	config	A config object for which this user_input is provided.
value		Value for the config. Type depends on Config type.

## **3.13.3 Instance**

An instance created for cluster.

Property	Type	Description
instance_id	string	Unique instance identifier.
instance_name	string	OpenStack Instance name.
internal_ip	string	IP to communicate with other instances.
management_ip	string	IP of instance, accessible outside of internal network.
volumes	list	List of volumes attached to instance. Empty if ephemeral drive is used.
nova_info	object	Nova Instance object.
username	string	Username, that Sahara uses for establishing remote connections to instance.
hostname	string	Same as instance_name.
fqdn	string	Fully qualified domain name for this instance.
remote	helpers	Object with helpers for performing remote operations

3.13. Object Model 81

# 3.13.4 Node Group

Group of instances.

Property	Type	Description	
name	string	Name of this Node Group in Cluster.	
flavor_id	string	OpenStack Flavor used to boot instances.	
image_id	string	Image id used to boot instances.	
node_processes	list	List of processes running on each instance.	
node_configs	dict	Configs dictionary, applied to instances.	
vol-	int	Number of volumes mounted to each instance. 0 means use ephemeral drive.	
umes_per_node			
volumes_size	int	Size of each volume (GB).	
vol-	string	Prefix added to mount path of each volume.	
umes_mount_prefix			
floating_ip_pool	string	Floating IP Pool name. All instances in the Node Group will have Floating IPs	
		assigned from this pool.	
count	int	Number of instances in this Node Group.	
username	string	Username used by Sahara to establish remote connections to instances.	
configuration	dict	Merged dictionary of node configurations and cluster configurations.	
storage_paths	list	List of directories where storage should be placed.	

## 3.13.5 Cluster

Contains all relevant info about cluster. This object is is provided to the plugin for both cluster creation and scaling. The "Cluster Lifecycle" section below further specifies which fields are filled at which moment.

Property	Туре	Description
name	string	Cluster name.
tenant_id	string	OpenStack Tenant id where this Cluster is available.
plugin_name	string	Plugin name.
hadoop_version	string	Hadoop version running on instances.
default_image_id	string	OpenStack image used to boot instances.
node_groups	list	List of Node Groups.
cluster_configs	dict	Dictionary of Cluster scoped configurations.
cluster_template_id	string	Cluster Template used for Node Groups and Configurations.
user_keypair_id	string	OpenStack keypair added to instances to make them accessible for user.
neu-	string	Neutron network ID. Instances will get fixed IPs in this network if
tron_management_network		'use_neutron' config is set to True.
anti_affinity	list	List of processes that will be run on different hosts.
description	string	Cluster Description.
info	dict	Dictionary for additional information.

## 3.13.6 Validation Error

Describes what is wrong with one of the values provided by user.

Property	Type	Description
config	config	A config object that is not valid.
error message	string	Message that describes what exactly is wrong.

# 3.14 Elastic Data Processing (EDP) SPI

EDP job engine objects provide methods for creating, monitoring, and terminating jobs on Sahara clusters. Provisioning plugins that support EDP must return an EDP job engine object from the *get\_edp\_engine(cluster, job\_type)* method described in *Plugin SPI*.

Sahara provides subclasses of the base job engine interface that support EDP on clusters running Oozie or on Spark standalone clusters. These are described below.

# **3.14.1 Job Types**

Some of the methods below test job type. Sahara supports the following string values for job types:

- Hive
- Java
- Pig
- MapReduce
- · MapReduce.Streaming
- Spark
- Shell

Note, constants for job types are defined in sahara.utils.edp

### 3.14.2 Job Status Values

Several of the methods below return a job status value. A job status value is a dictionary of the form:

{'status': *job\_status\_value*}

where *job\_status\_value* is one of the following string values:

- DONEWITHERROR
- FAILED
- TOBEKILLED
- KILLED
- PENDING
- RUNNING
- SUCCEEDED

Note, constants for job status are defined in sahara.utils.edp

## 3.14.3 EDP Job Engine Interface

The sahara.service.edp.base\_engine.JobEngine class is an abstract class with the following interface:

#### cancel\_job(job\_execution)

Stops the running job whose id is stored in the job\_execution object.

Returns: None if the operation was unsuccessful or an updated job status value

### get\_job\_status(job\_execution)

Returns the current status of the job whose id is stored in the job\_execution object.

Returns: a job status value

### run\_job(job\_execution)

Starts the job described by the job\_execution object

Returns: a tuple of the form (job\_id, job\_status\_value, job\_extra\_info)

- job\_id is required and must be a string that allows the EDP engine to uniquely identify the job.
- *job\_status\_value* may be None or a job status value
- *job\_extra\_info* may be None or optionally a dictionary that the EDP engine uses to store extra information on the job\_execution\_object.

### validate\_job\_execution(cluster, job, data)

Checks whether or not the job can run on the cluster with the specified data. Data contains values passed to the /jobs/<job\_id>/execute REST API method during job launch. If the job cannot run for any reason, including job configuration, cluster configuration, or invalid data, this method should raise an exception.

Returns: None

## get\_possible\_job\_config(job\_type)

Returns hints used by the Sahara UI to prompt users for values when configuring and launching a job. Note that no hints are required.

See *Elastic Data Processing (EDP)* for more information on how configuration values, parameters, and arguments are used by different job types.

Returns: a dictionary of the following form, containing hints for configs, parameters, and arguments for the job type:

```
{'job_config': {'configs': [], 'params': {}, 'args': []}}
```

- args is a list of strings
- params contains simple key/value pairs
- each item in configs is a dictionary with entries for 'name' (required), 'value', and 'description'

#### get\_supported\_job\_types()

This method returns the job types that the engine supports. Not all engines will support all job types.

Returns: a list of job types supported by the engine

# 3.14.4 Oozie Job Engine Interface

The sahara.service.edp.oozie.engine.OozieJobEngine class is derived from JobEngine. It provides implementations for all of the methods in the base interface but adds a few more abstract methods.

Note, the *validate\_job\_execution(cluster, job, data)* method does basic checks on the job configuration but probably should be overloaded to include additional checks on the cluster configuration. For example, the job engines for plugins that support Oozie add checks to make sure that the Oozie service is up and running.

#### get\_hdfs\_user()

Oozie uses HDFS to distribute job files. This method gives the name of the account that is used on the data nodes to access HDFS (such as 'hadoop' or 'hdfs'). The Oozie job engine expects that HDFS contains a directory for this user under /user/

Returns: a string giving the username for the account used to access HDFS on the cluster.

#### create hdfs dir(remote, dir name)

The remote object *remote* references a node in the cluster. This method creates the HDFS directory *dir\_name* under the user specified by *get\_hdfs\_user()* in the HDFS accessible from the specified node. For example, if the HDFS user is 'hadoop' and the dir\_name is 'test' this method would create '/user/hadoop/test'.

The reason that this method is broken out in the interface as an abstract method is that different versions of Hadoop treat path creation differently.

Returns: None

#### get oozie server uri(cluster)

Returns the full URI for the Oozie server, for example <a href="http://my\_oozie\_host:11000/oozie">http://my\_oozie\_host:11000/oozie</a>. This URI is used by an Oozie client to send commands and queries to the Oozie server.

Returns: a string giving the Oozie server URI.

#### get\_oozie\_server(self, cluster)

Returns the node instance for the host in the cluster running the Oozie server

Returns: a node instance

#### get name node uri(self, cluster)

Returns the full URI for the Hadoop NameNode, for example http://master\_node:8020.

Returns: a string giving the NameNode URI.

#### get resource manager uri(self, cluster)

Returns the full URI for the Hadoop JobTracker for Hadoop version 1 or the Hadoop ResourceManager for Hadoop version 2.

Returns: a string giving the JobTracker or ResourceManager URI

# 3.14.5 Spark Job Engine

The sahara.service.edp.spark.engine.SparkJobEngine class provides a full EDP implementation for Spark standalone clusters.

Note, the *validate\_job\_execution(cluster, job, data)* method does basic checks on the job configuration but probably should be overloaded to include additional checks on the cluster configuration. For example, the job engine returned by the Spark plugin checks that the Spark version is >= 1.0.0 to ensure that *spark-submit* is available.

### get\_driver\_classpath(self)

Returns driver class path.

Returns: a string of the following format '-driver-class-path class\_path\_value'

## 3.15 Sahara Cluster Statuses Overview

All Sahara Cluster operations are performed in multiple steps. A Cluster object has a Status attribute which changes when Sahara finishes one step of operations and starts another one. Also a Cluster object has a Status description attribute which changes each time when some error with the Cluster occurs.

#### Sahara supports three types of Cluster operations:

- · Create a new Cluster
- Scale/Shrink an existing Cluster
- · Delete an existing Cluster

### 3.15.1 Creating a new Cluster

#### 1. Validating

Before performing any operations with OpenStack environment, Sahara validates user input.

### There are two types of validations, that are done:

• Check that a request contains all necessary fields and that the request does not violate

#### any constraints like unique naming, etc.

Plugin check (optional). The provisioning Plugin may also perform any specific checks like Cluster topology validation.

If any of the validations fails during creating, the Cluster will still be kept in the database with an Error status. If any validations fails during scaling the Active Cluster, it will be kept with an Active status. In both cases status description will contain message about the reasons of failure.

### 2. InfraUpdating

This status means that the Provisioning plugin performs some infrastructural updates.

### 3. Spawning

Sahara sends requests to OpenStack for all resources to be created:

- VMs
- Volumes
- Floating IPs (if Sahara is configured to use Floating IPs)

It takes some time for OpenStack to schedule all the required VMs and Volumes, so Sahara will wait until all of them are in an Active state.

### 4. Waiting

Sahara waits while VMs' operating systems boot up and all internal infrastructure components like networks and volumes are attached and ready to use.

#### 5. Preparing

Sahara prepares a Cluster for starting. This step includes generating the /etc/hosts file, so that all instances can access each other by a hostname. Also Sahara updates the authorized\_keys file on each VM, so that communication can be done without passwords.

### 6. Configuring

Sahara pushes service configurations to VMs. Both XML based configurations and environmental variables are set on this step.

### 7. Starting

Sahara is starting Hadoop services on Cluster's VMs.

### 8. Active

Active status means that a Cluster has started successfully and is ready to run Jobs.

# 3.15.2 Scaling/Shrinking an existing Cluster

#### 1. Validating

Sahara checks the scale/shrink request for validity. The Plugin method called for performing Plugin specific checks is different from creation validation method.

#### 2. Scaling

Sahara performs database operations updating all affected existing Node Groups and creating new ones.

#### 3. Adding Instances

State similar to Spawning while Custer creation. Sahara adds required amount of VMs to existing Node Groups and creates new Node Groups.

### 4. Configuring

State similar to Configuring while Cluster creation. New instances are being configured in the same manner as already existing ones. Existing Cluster VMs are also updated with a new /etc/hosts file.

### 5. Decommissioning

Sahara stops Hadoop services on VMs that will be deleted from a Cluster. Decommissioning a Data Node may take some time because Hadoop rearranges data replicas around the Cluster, so that no data will be lost after that VM is deleted.

### 6. Deleting Instances

Sahara sends requests to OpenStack to release unneeded resources:

- VMs
- Volumes
- Floating IPs (if they are used)

### 7. Active

The same Active as after Cluster creation.

# 3.15.3 Deleting an existing Cluster

### 1. Deleting

The only step, that releases all Cluster's resources and removes it from the database.

### 3.15.4 Error State

If the Cluster creation fails, the Cluster will get into an Error state. This state means the Cluster may not be able to perform any operations normally. This cluster will stay in the database until it is manually deleted. The reason for failure may be found in the Sahara logs. Also status description will contain short information about reasons of failure.

If an error occurs during the Adding Instances operation, Sahara will first try to rollback this operation. If a rollback is impossible or fails itself, then the Cluster will also go into an Error state. If a rollback was successful, Cluster will get into an Active state and status description will contain short message about the reasons of Adding Instances failure.

### **Other Resources**

# 3.16 Project hosting

Launchpad hosts the Sahara project. The Sahara project homepage on Launchpad is http://launchpad.net/sahara.

# 3.16.1 Launchpad credentials

Creating a login on Launchpad is important even if you don't use the Launchpad site itself, since Launchpad credentials are used for logging in on several OpenStack-related sites. These sites include:

- Wiki
- Gerrit (see Code Reviews with Gerrit)
- Jenkins (see Continuous Integration with Jenkins)

### 3.16.2 Mailing list

The mailing list email is openstack-dev@lists.openstack.org with subject prefix [sahara]. To participate in the mailing list subscribe to the list at http://lists.openstack.org/cgi-bin/mailman/listinfo

## 3.16.3 Bug tracking

Report Sahara bugs at https://bugs.launchpad.net/sahara

# 3.16.4 Feature requests (Blueprints)

Sahara uses specs to track feature requests. Blueprints are at https://blueprints.launchpad.net/sahara. They provide a high-level summary of proposed changes and track associated commits. Sahara also uses specs for in-depth descriptions and discussions of blueprints. Specs follow a defined format and are submitted as change requests to the openstack/sahara-specs repository. Every blueprint should have an associated spec that is agreed on and merged to the sahara-specs repository before it is approved.

### 3.16.5 Technical support

Sahara uses Ask OpenStack to track Sahara technical support questions. Questions related to Sahara should be tagged with 'sahara'.

### 3.17 Code Reviews with Gerrit

Sahara uses the Gerrit tool to review proposed code changes. The review site is http://review.openstack.org.

Gerrit is a complete replacement for Github pull requests. All Github pull requests to the Sahara repository will be ignored.

See Gerrit Workflow Quick Reference for information about how to get started using Gerrit. See Development Workflow for more detailed documentation on how to work with Gerrit.

# 3.18 Continuous Integration with Jenkins

Each change made to Sahara core code is tested with unit and integration tests and style checks flake8.

Unit tests and style checks are performed on public OpenStack Jenkins managed by Zuul. Unit tests are checked using python 2.7.

The result of those checks and Unit tests are +1 or -1 to Verify column in a code review from Jenkins user.

Integration tests check CRUD operations for Image Registry, Templates and Clusters. Also a test job is launched on a created Cluster to verify Hadoop work.

All integration tests are launched by Jenkins on the internal Mirantis OpenStack Lab. Jenkins keeps a pool of VMs to run tests in parallel. Even with the pool of VMs integration testing may take a while. Jenkins is controlled for the most part by Zuul which determines what jobs are run when. Zuul status is available by address: Zuul Status. For more information see: Sahara Hadoop Cluster CI.

The integration tests result is +1 or -1 to Verify column in a code review from Sahara Hadoop Cluster CI user.

You can put *sahara-ci-recheck* in comment, if you want to recheck sahara-ci jobs. Also, you can put *recheck* in comment, if you want to recheck both jenkins and sahara-ci jobs.
